# Review of direct Dark Matter searches

Marco Selvi  
INFN Bologna

Preparing for Dark Matter discovery, 12<sup>th</sup> June 2018, Göteborg

# Outline

---

- Review of WIMP kinematics (no Axions in this talk, sorry)
- Generalities on signal and backgrounds
- Most effective detection techniques
- Review of recent results from direct DM detection experiments

\* many thanks to  
E. Aprile, L. Baudis, G. Fiorillo, T. Marrodan,  
K. Palladino, K. Ni, M. Schumann  
for useful materials used in this review

# Outline

---

- Review of WIMP kinematics (no Axions in this talk, sorry)
- Generalities on signal and backgrounds
- Most effective detection techniques
- Review of recent results from direct DM detection experiments

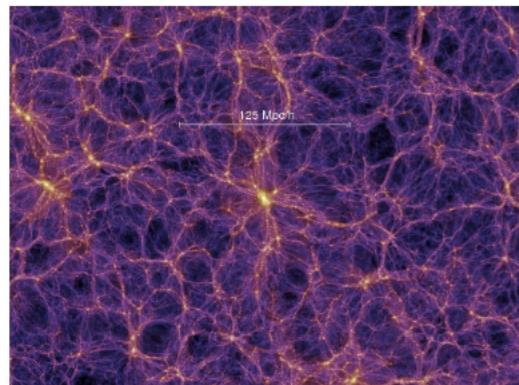

Usual disclaimers of these kinds of review talks:  
not complete, biased, personal view, etc

\* many thanks to  
E. Aprile, L. Baudis, G. Fiorillo, T. Marrodan,  
K. Palladino, K. Ni, M. Schumann  
for useful materials used in this review

# Particle Dark Matter

An elementary particle?

- **Massive** → explain gravitational effects
- **Neutral** → no EM interaction & **Weakly** interacting at most
- **Stable** or long-lived → not to have decayed by now
- **Cold** (moving non-relativistically) or **warm** → structure formation

In the standard model of particle physics:  
**Neutrino** fulfil most  
but it is a **hot** dark matter candidate

→ Models beyond SM typically predict NEW particles

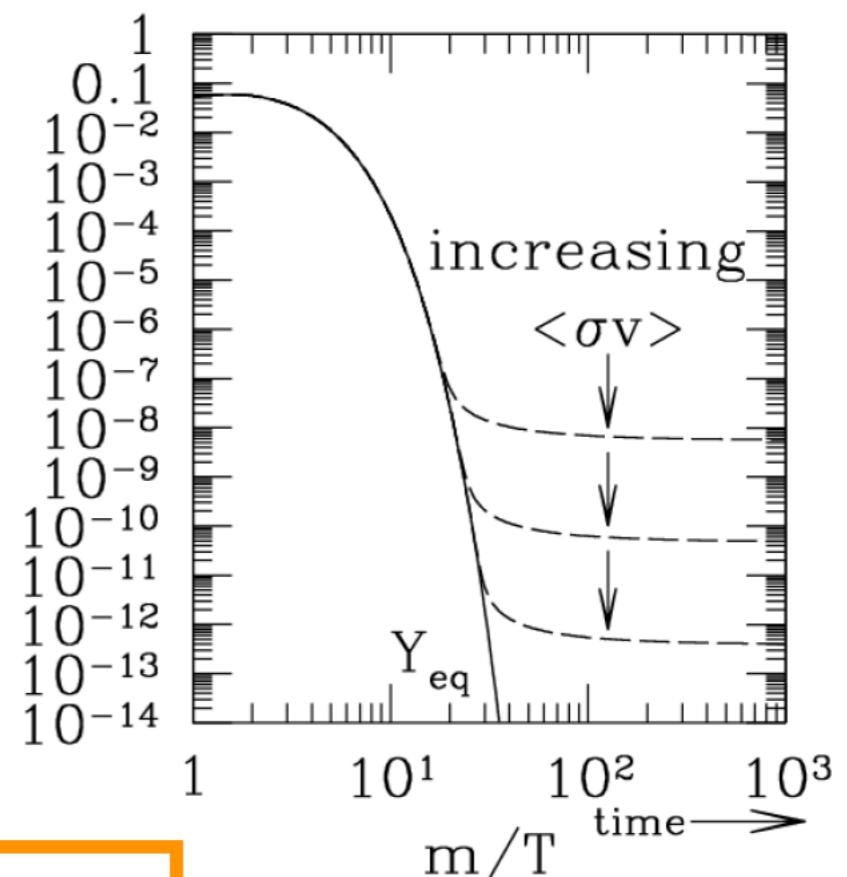

**Neutralino** in Supersymmetry, gravitino, **Axion**, **LKP** in extra dimensions,  
**Sterile neutrino**, **Super-heavy dark matter** and many others

# WIMPs

Well motivated theoretical approach:

**WIMP**  
(Weakly Interacting Massive Particle)

- In the early Universe particles are in thermal equilibrium:  
**creation  $\leftrightarrow$  annihilation**  
 $\chi\bar{\chi} \leftrightarrow e^+e^-, \mu^+\mu^-, q\bar{q}, W^+W^-, ZZ\dots$
- When annihilation rate  $\ll$  Universe expansion rate  $\rightarrow$  '**freeze out**'
- Correct relic density for an annihilation rate  $\sim$  weak scale

In this talk I will focus mostly on **WIMP direct detection**

# Dark Matter searches

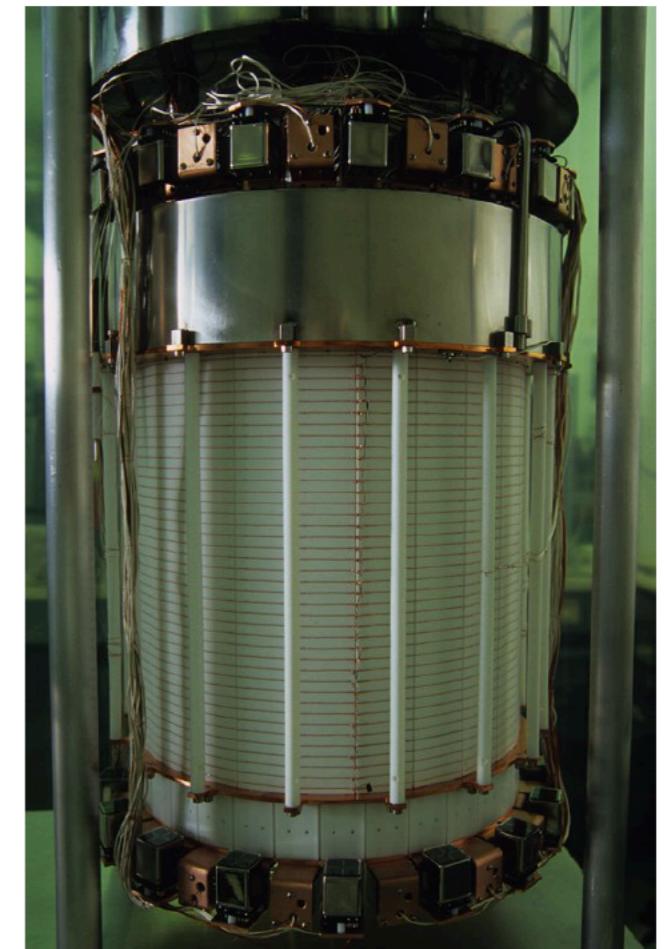

- Production at LHC

- Indirect detection

- Direct detection

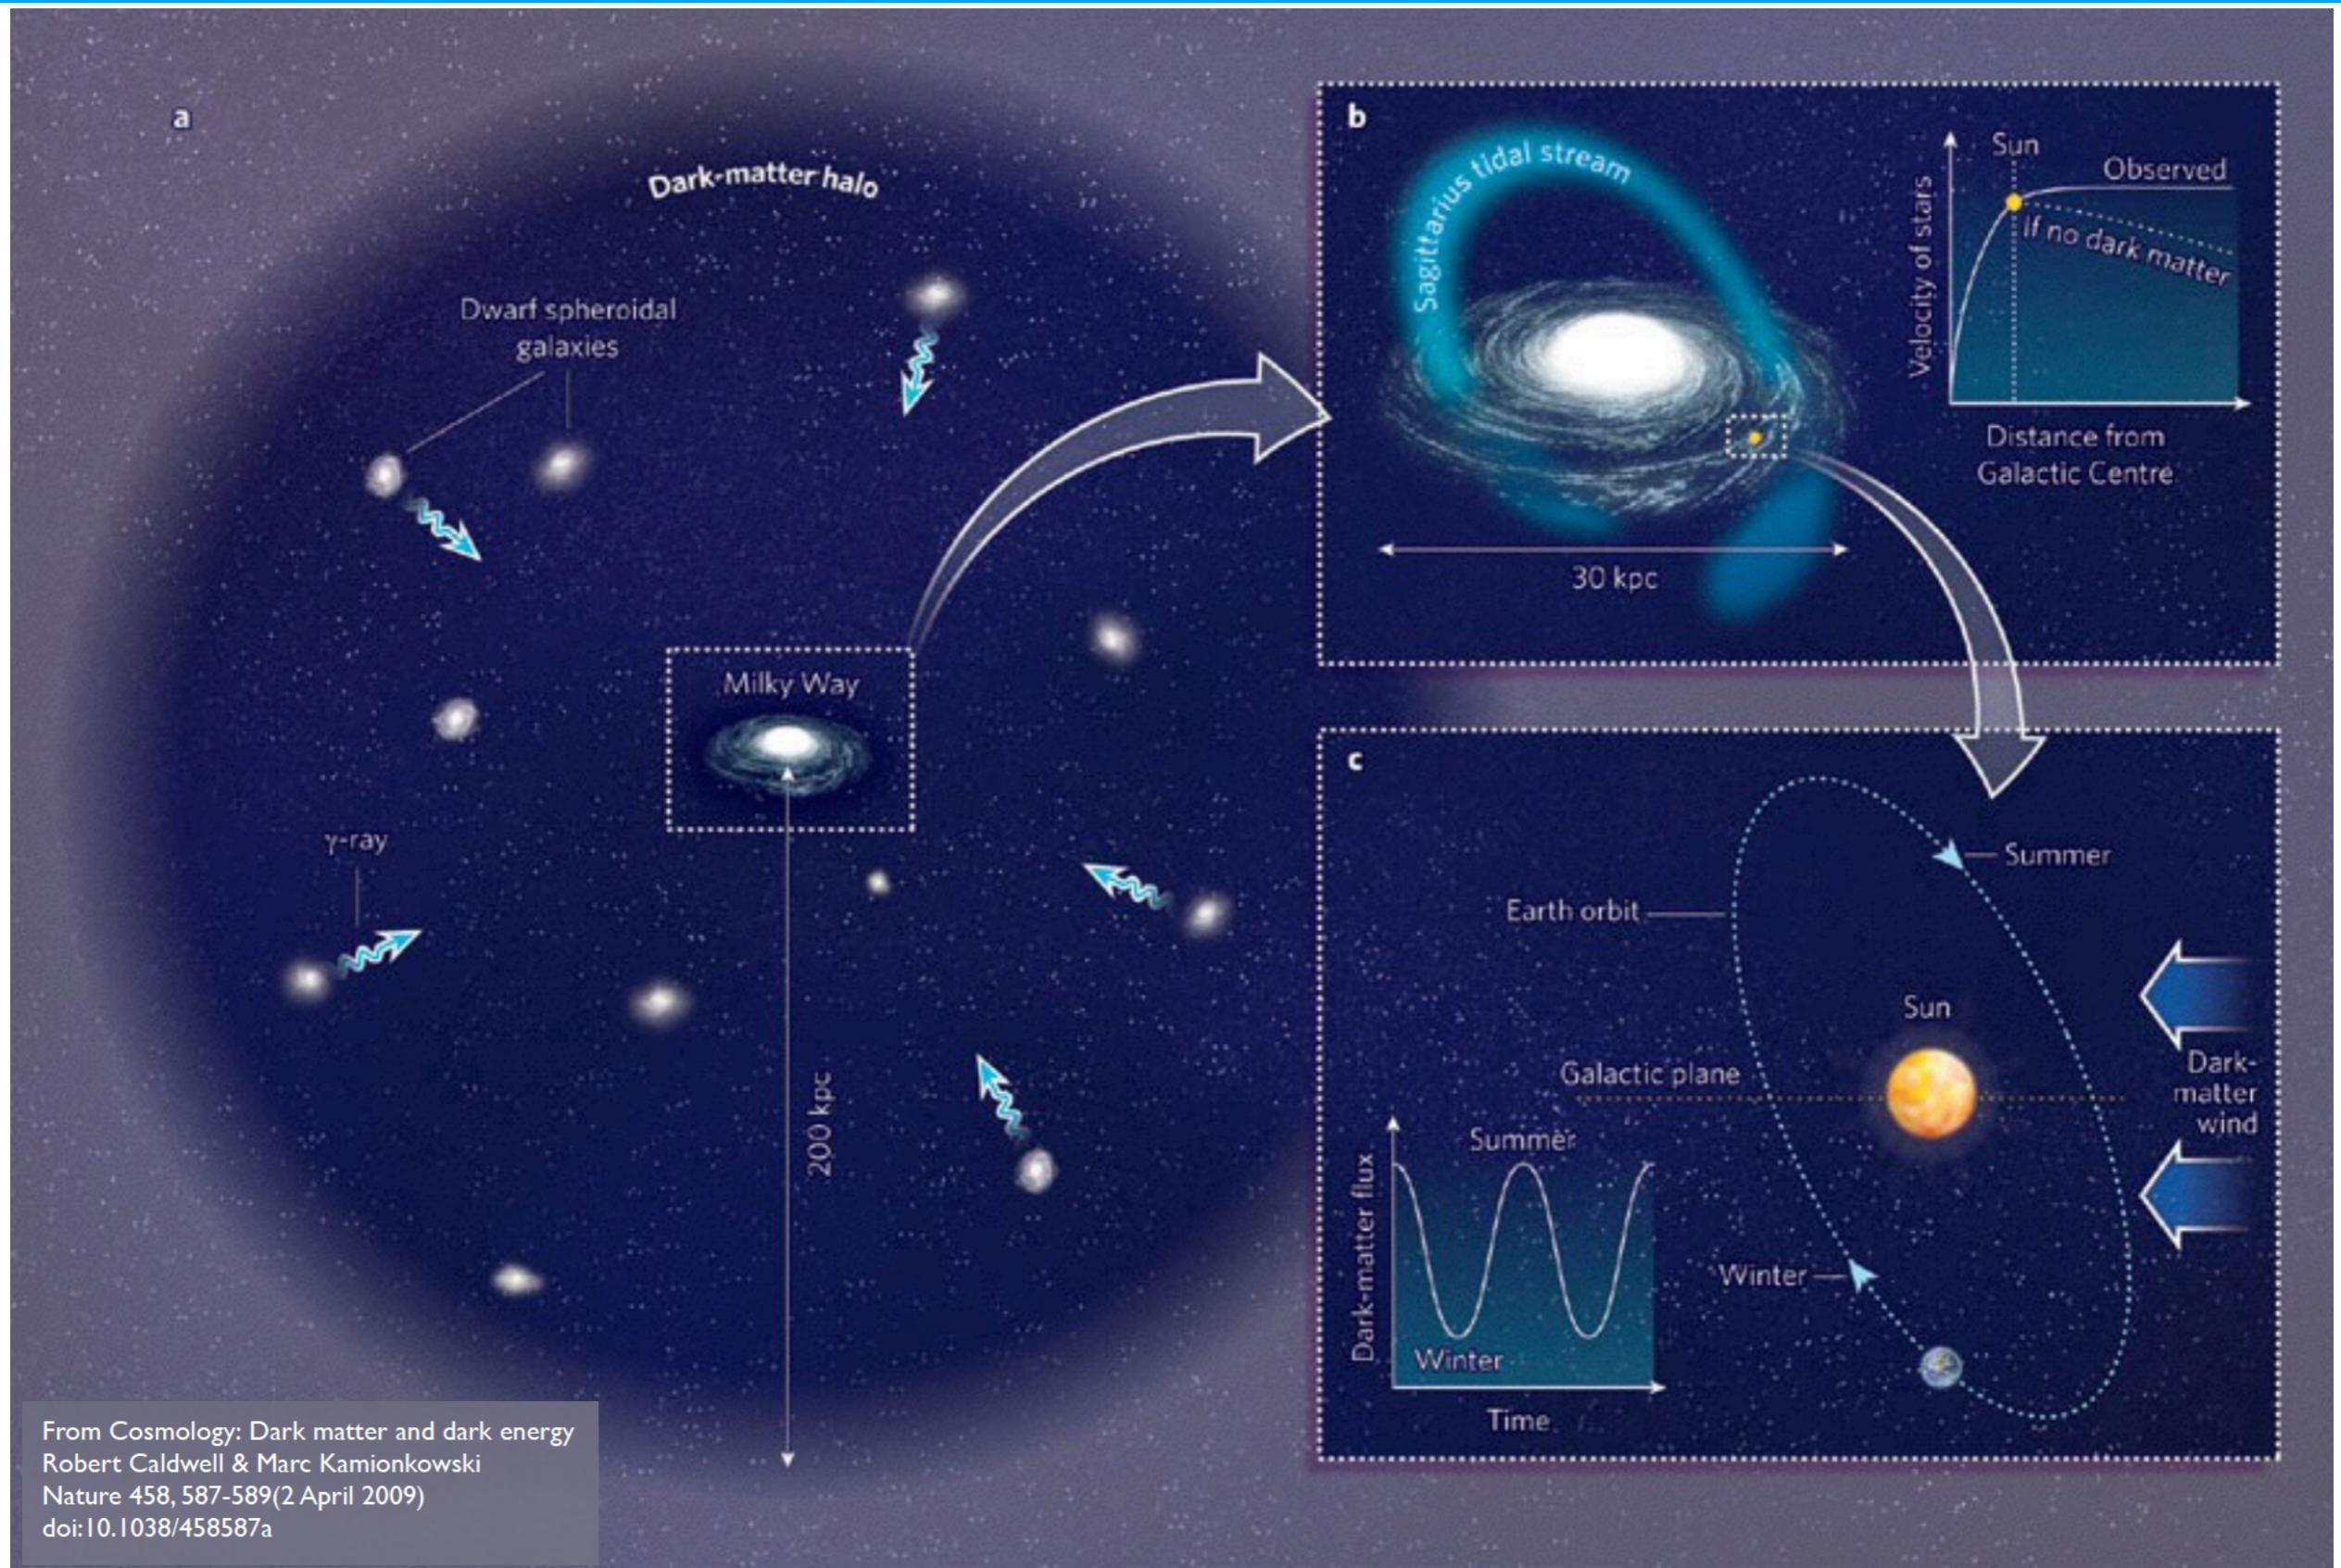

$p + p \rightarrow \chi\bar{\chi} + \text{a lot}$

$\chi\chi \rightarrow \gamma\gamma, q\bar{q}, \dots$

$\chi N \rightarrow \chi N$

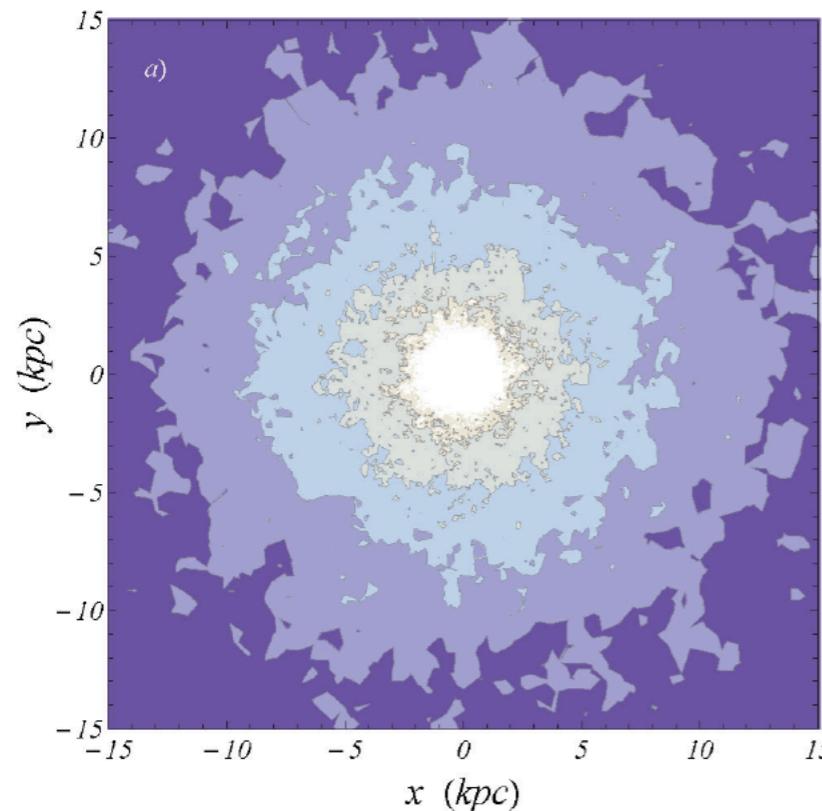

# We live in a dark matter halo

# WIMP density and velocity distribution

## WIMPs in the galactic halo

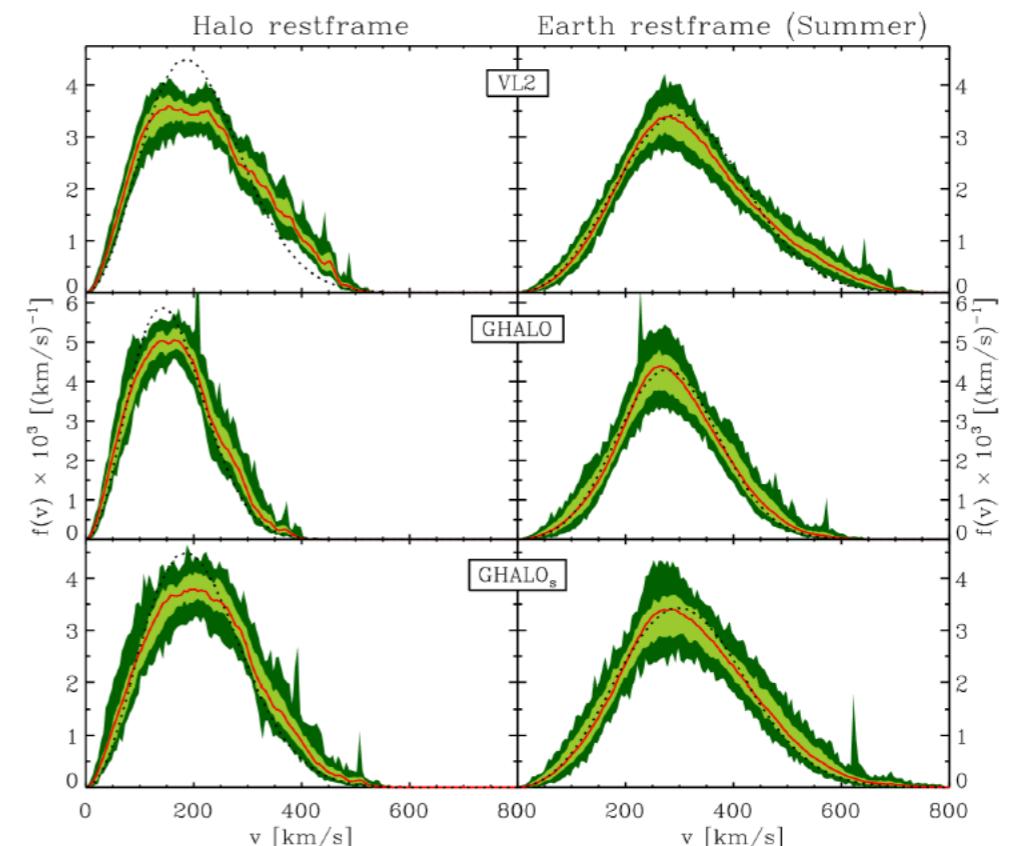

Density map of the dark matter halo  
 $\rho = [0.1, 0.3, 1.0, 3.0] \text{ GeV cm}^{-3}$

High-resolution cosmological simulation with baryons: F.S. Ling et al, JCAP02 (2010) 012

$$\rho_{\text{local}} \sim 0.3 \text{ GeV} \cdot \text{cm}^{-3}$$

### Velocity distribution of WIMPs in the galaxy

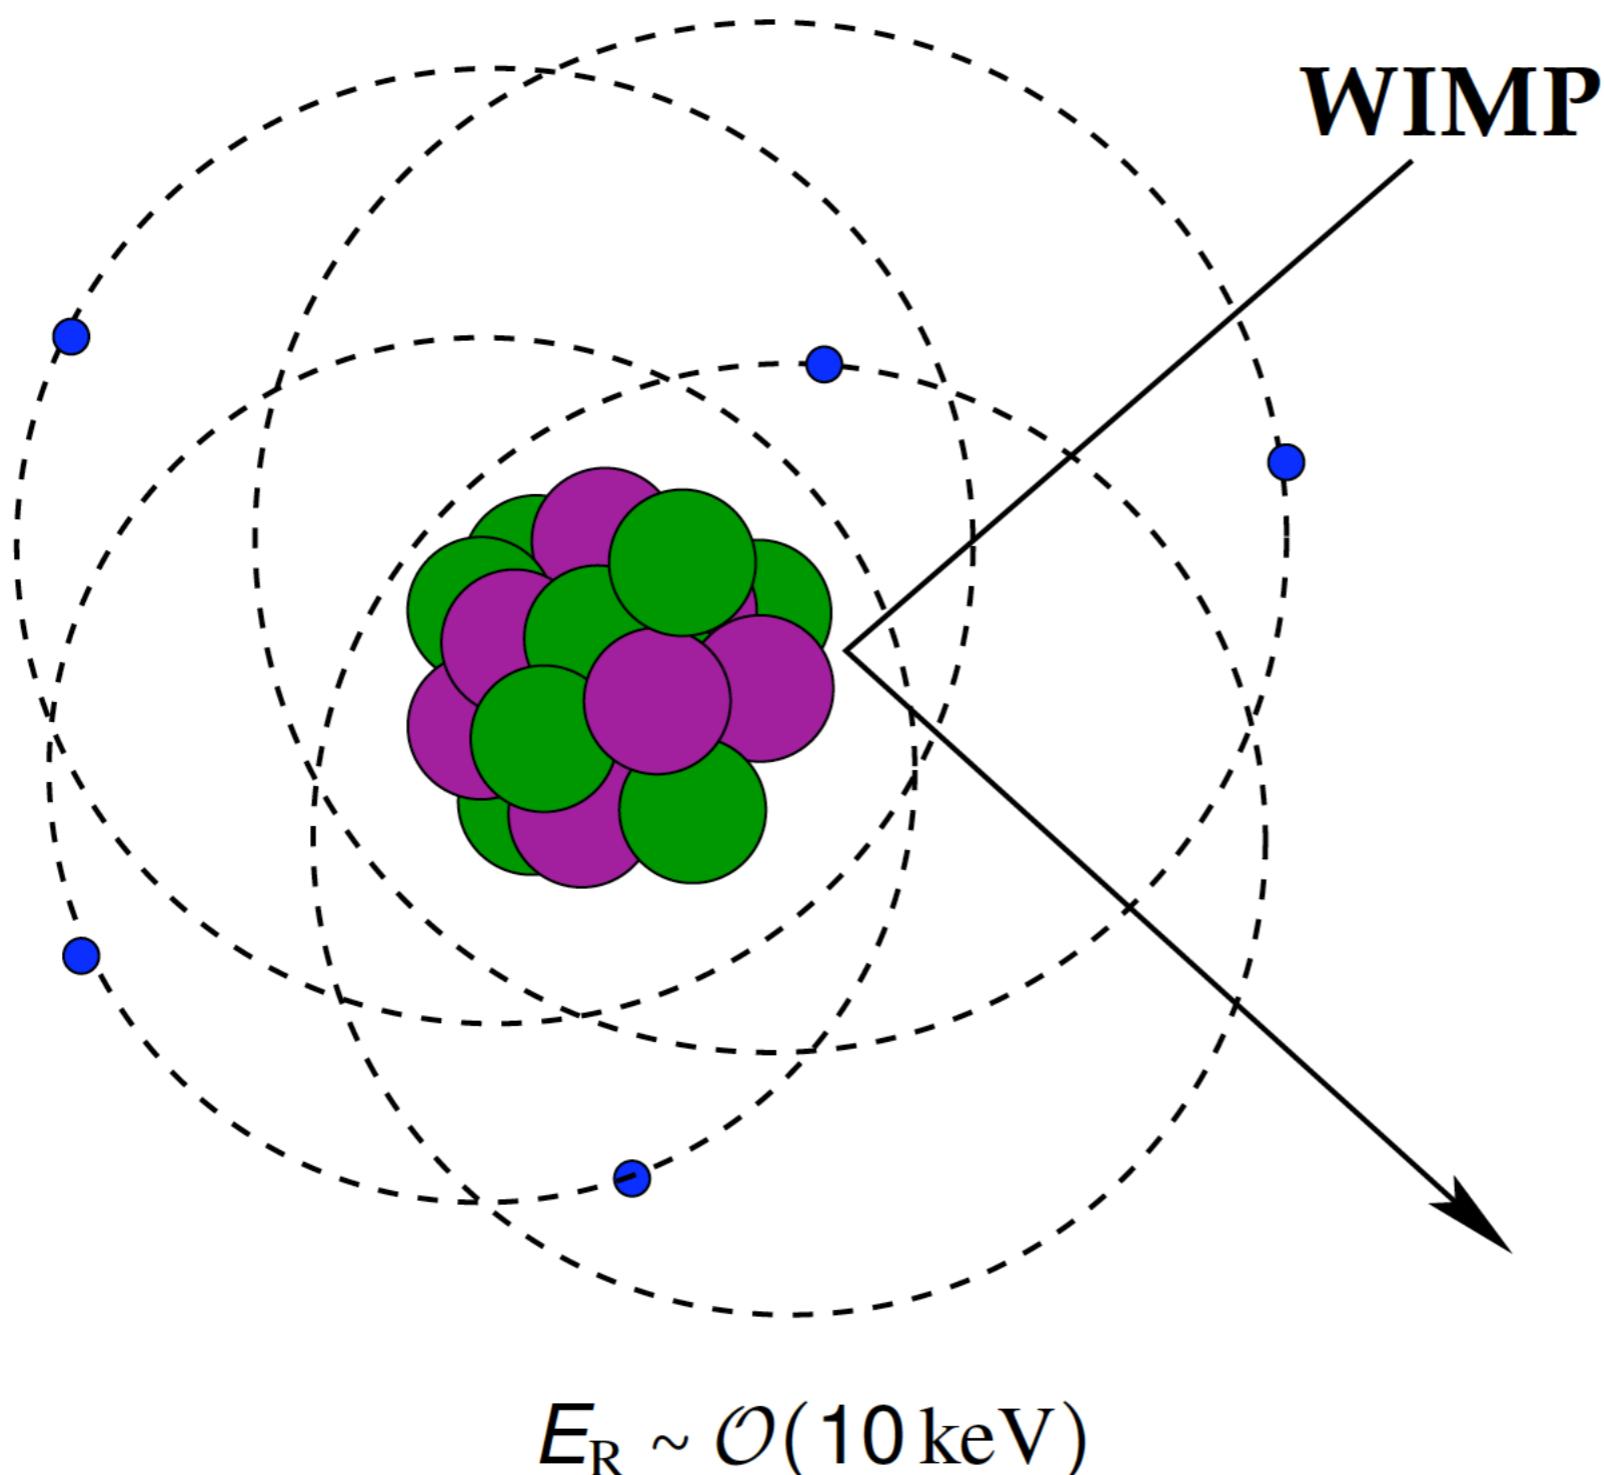

M. Kuhlen et al, JCAP02 (2010) 030

From cosmological simulations of galaxy formation: departures from the simplest case of a Maxwell-Boltzmann distribution

In direct detection experiments, mostly a simple MB distribution, truncated at  $v_{\text{esc}}$ , is used in the sensitivity calculation

# Direct Dark Matter Detection

$$R \propto N_T \frac{\rho_0}{m_X} \sigma \langle v \rangle$$

# The standard halo model

Isotropic, isothermal sphere with a Maxwellian velocity distribution

$$f(v) = N \cdot \exp\left(\frac{-3|v|^2}{2\sigma^2}\right)$$

usually truncated  $f(v) = 0$  for  $|v| > v_{\text{esc}}$

Local density  $\rho_0 = 0.3 \text{ GeV/cm}^3 = 0.008 M_{\odot}/pc^3 = 5 \cdot 10^{-23} \text{ g/cm}^3$   
determined via mass modelling of the Milky Way

About 1 WIMP in a coffee cup (assuming  $m_{\chi} \sim 100 \text{ GeV}/c^2$ )

Circular velocity  $v_c = 220 \text{ km/s}$   
with radial dispersion velocity  $\sigma_r = v_c/\sqrt{2}$

Escape velocity  $v_{\text{esc}} = 544 \text{ km/s}$   
determined from the speed of high velocity stars (RAVE)

# Expected Rates

---

$$\frac{dR}{dE}(E, t) = \frac{\rho_0}{m_\chi \cdot m_A} \cdot \int \mathbf{v} \cdot f(\mathbf{v}, t) \cdot \frac{d\sigma}{dE}(E, \mathbf{v}) d^3 v$$

## Astrophysical parameters:

- $\rho_0$  = local density of the dark matter in the Milky Way
- $f(\mathbf{v}, t)$  = WIMP velocity distribution

## Parameters of interest:

- $m_\chi$  = WIMP mass ( $\sim 100 \text{ GeV}/c^2$ )
- $\sigma$  = WIMP-nucleus elastic scattering cross section
  - Spin-independent interactions: coupling to nuclear mass
  - Spin-dependent interactions: coupling to nuclear spin

# Scattering Cross Section

- In general, interactions leading to WIMP-nucleus scattering are parameterized as:
  - **scalar interactions** (coupling to WIMP mass, from scalar, vector, tensor part of L)

$$\sigma_{SI} \sim \frac{\mu^2}{m_\chi^2} [Zf_p + (A - Z)f_n]^2$$

$f_p, f_n$ : scalar 4-fermion  
couplings to p and n

=> nuclei with large A favourable (but nuclear form factor corrections)

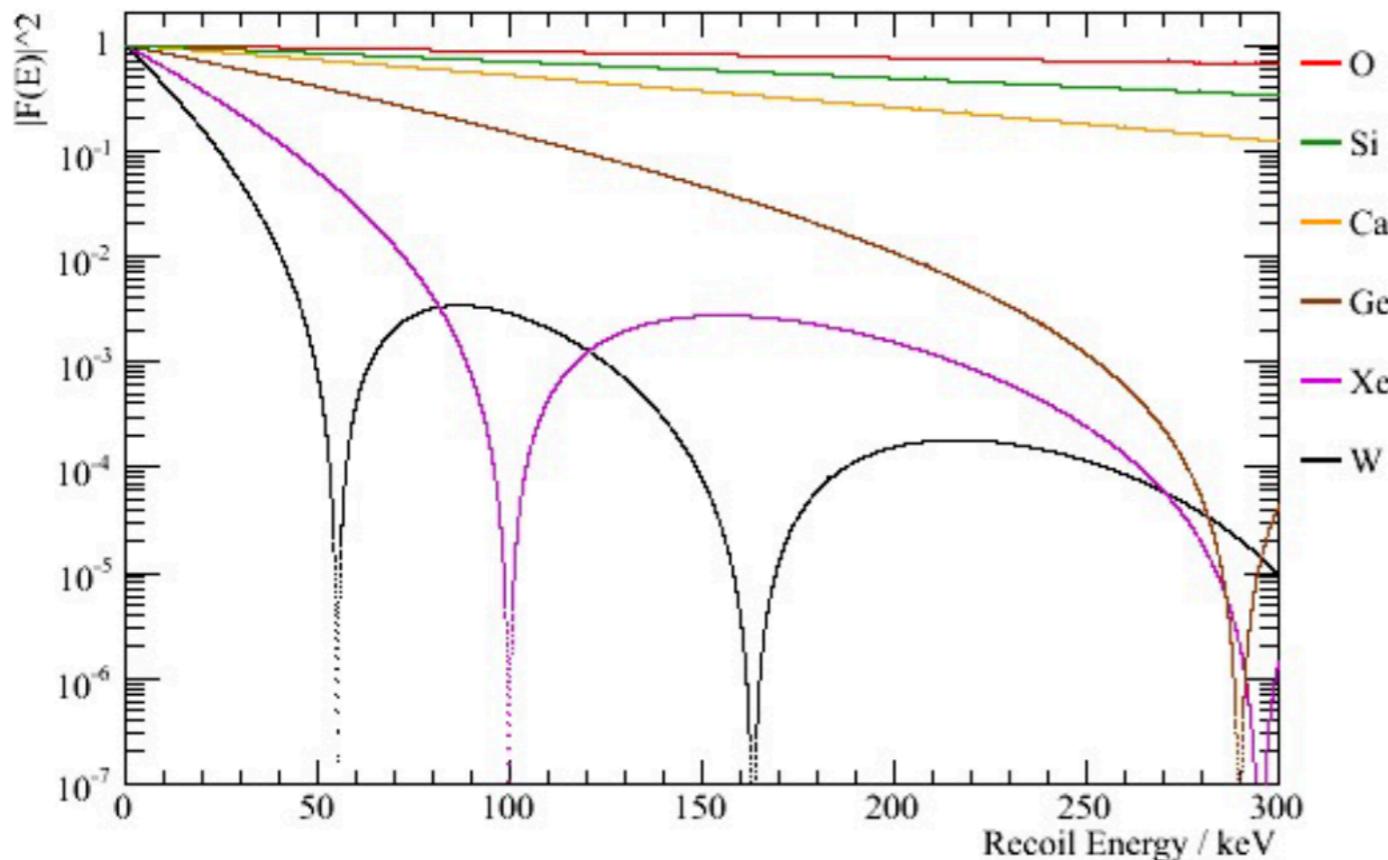

- **spin-spin interactions** (coupling to the nuclear spin  $J_N$ , from axial-vector part of L)

$$\sigma_{SD} \sim \mu^2 \frac{J_N + 1}{J_N} (a_p \langle S_p \rangle + a_n \langle S_n \rangle)^2$$

$a_p, a_n$ : effective couplings to p  
and n;  $\langle S_p \rangle$  and  $\langle S_n \rangle$   
expectation values of the p and n  
spins within the nucleus

=> nuclei with non-zero angular momentum (corrections due to spin structure functions)

# Correction: the Form Factor

With the Helm parametrization for the nuclear density the form factor is

$$F^2(Q) = \left[ \frac{3j_1(qR_1)}{qR_1} \right]^2 e^{-(qs)^2}$$

$j$  = 1st Bessel function

$s$  = nuclear skin thickness  $\sim 1$  fm

$R_1 \propto 1.14 A^{1/3} \sim 7 A^{1/3} \text{ GeV}^{-1}$

Form factor is important for large nuclei, such as Xe, W, etc.

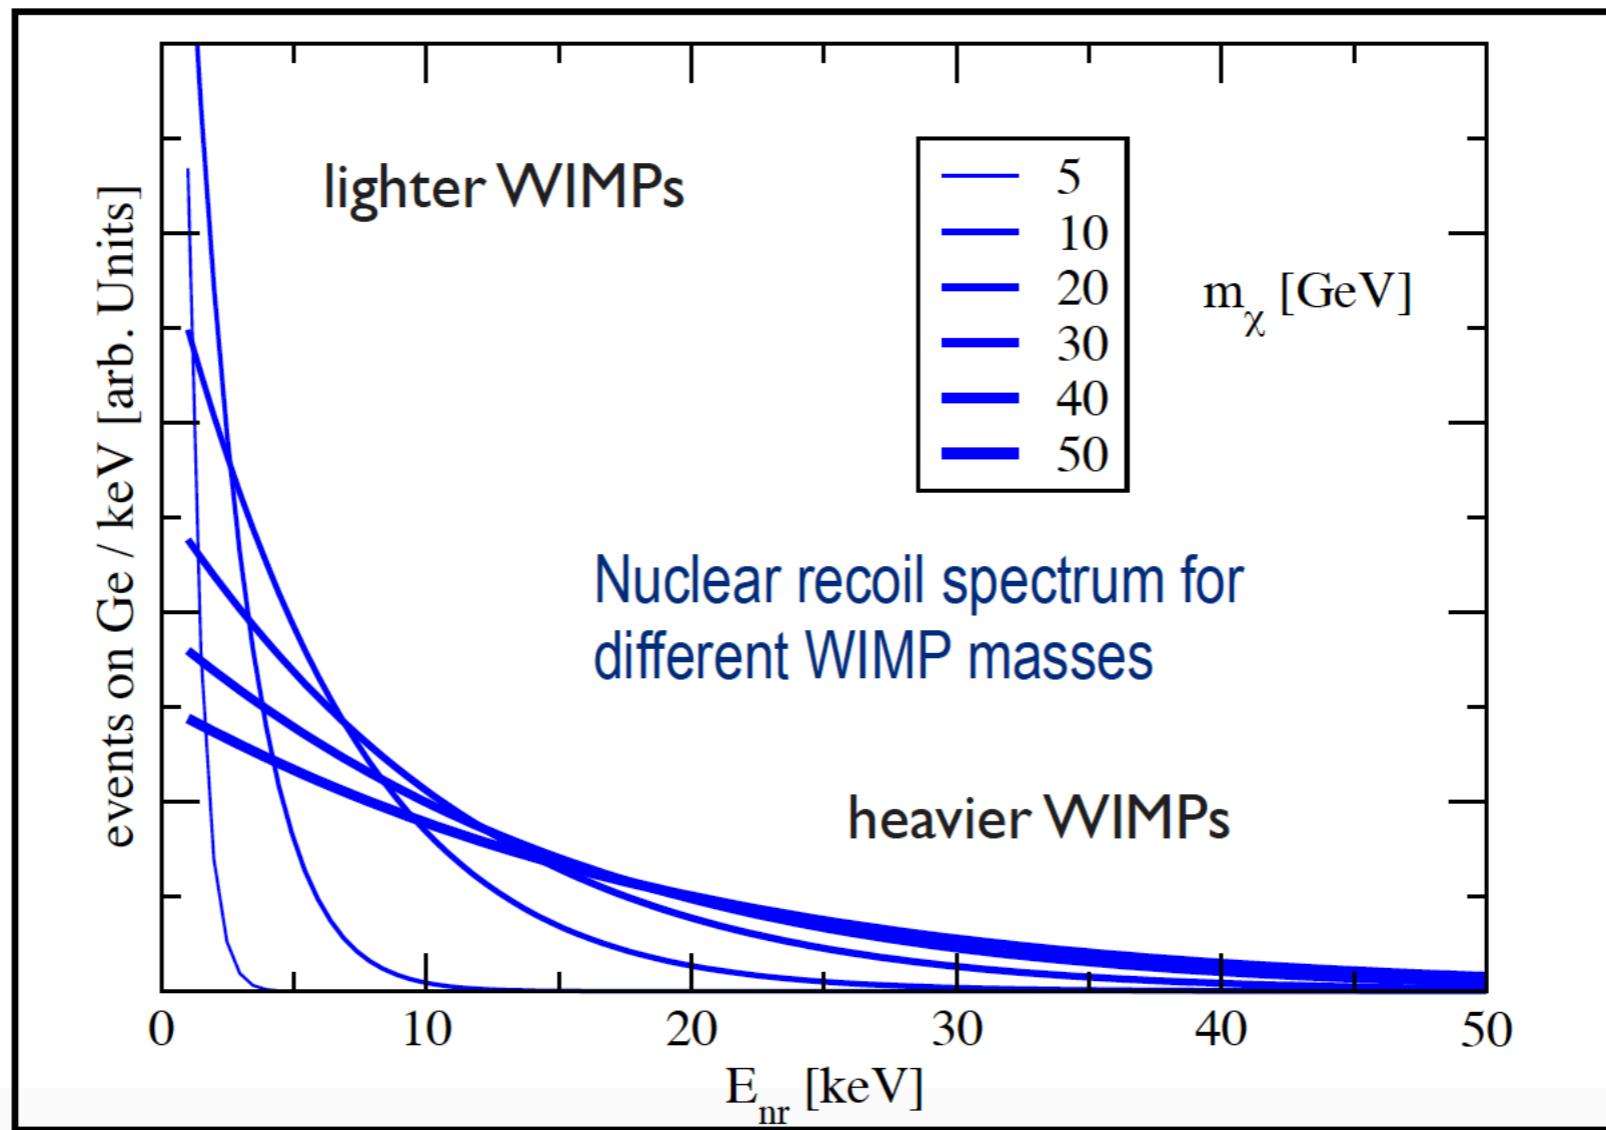

For these targets, a low energy threshold is essential to minimize Form factor suppression of rate

At the same time, the coherence of the scattering favors large nuclei

# Nuclear Recoil Energy Spectrum

Rate after integration over WIMP velocity distribution

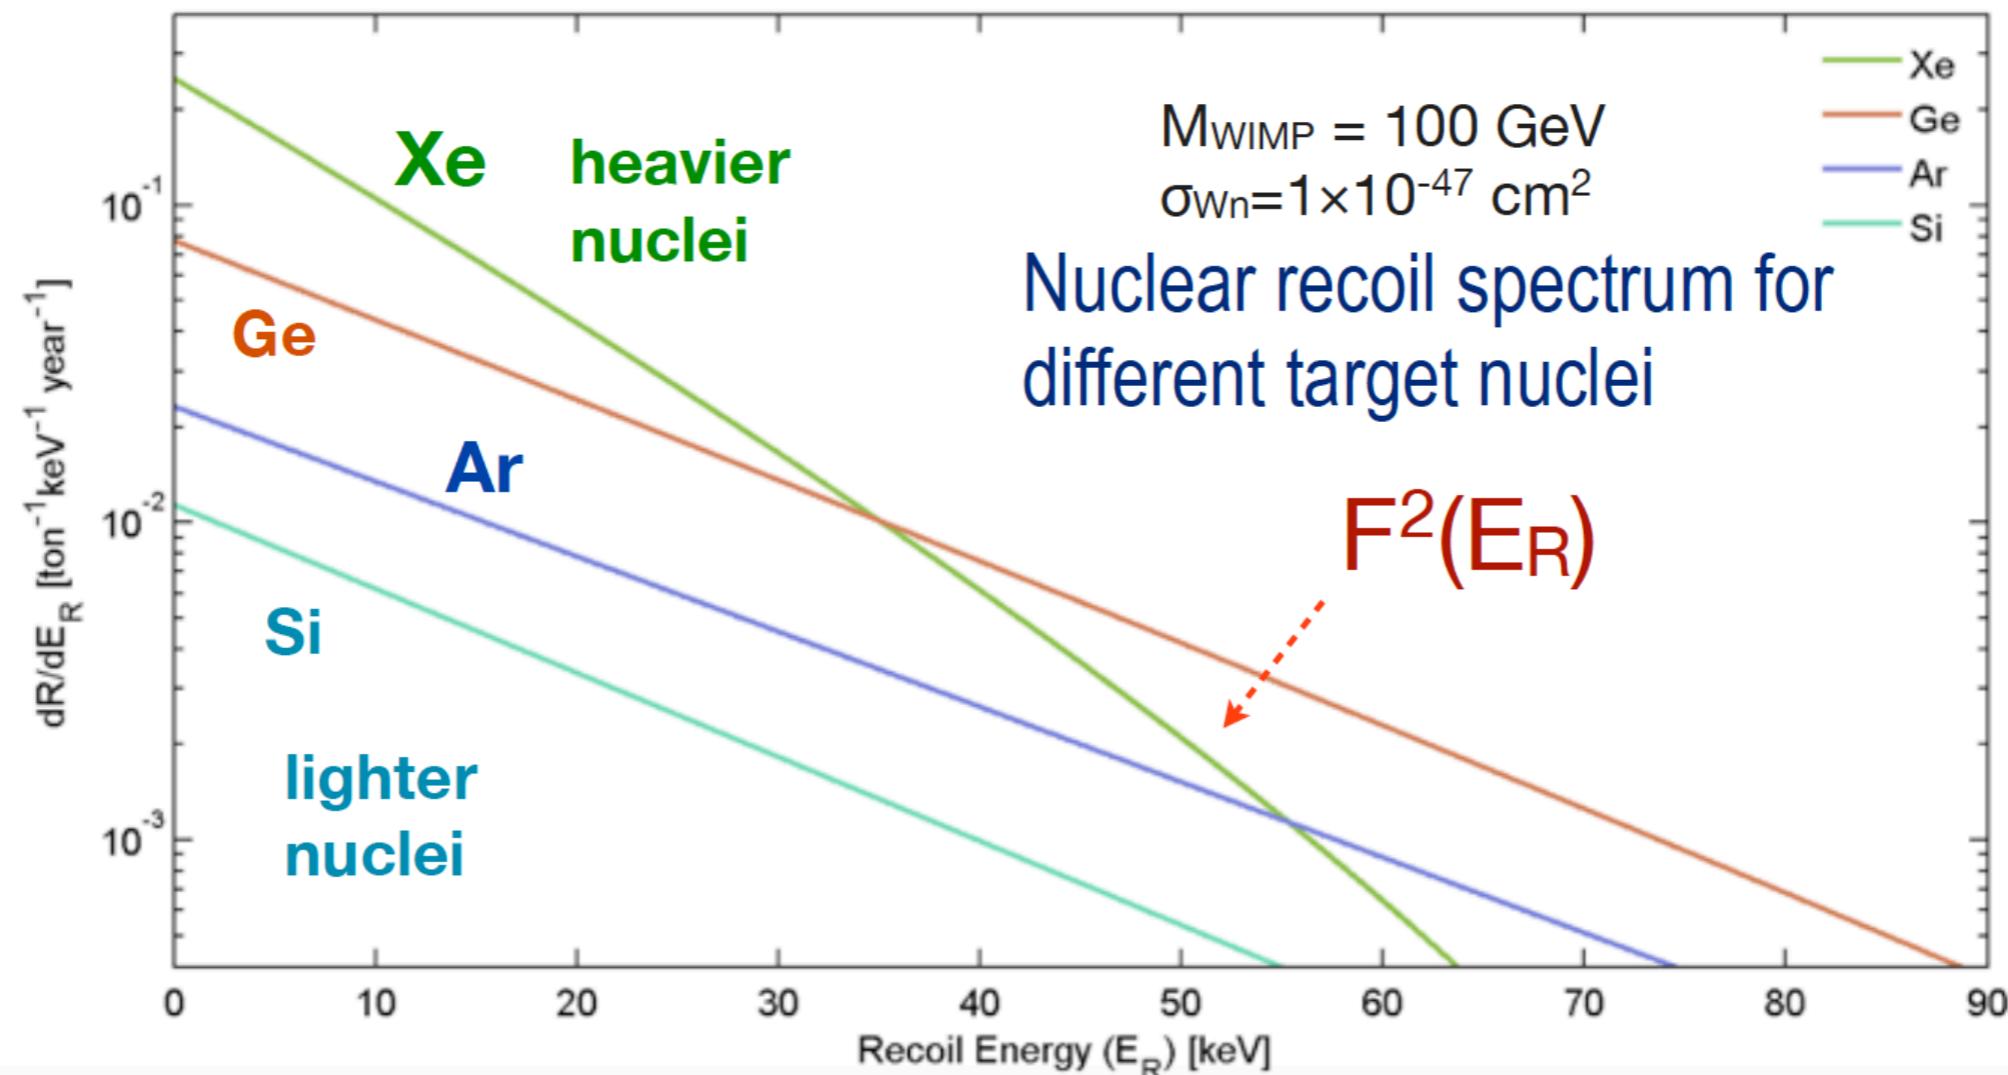

$$R \sim 0.13 \frac{\text{events}}{\text{kg year}} \left[ \frac{A}{100} \times \frac{\sigma_{WN}}{10^{-38} \text{ cm}^2} \times \frac{\langle v \rangle}{220 \text{ km s}^{-1}} \times \frac{\rho_0}{0.3 \text{ GeV cm}^{-3}} \right]$$

# Nuclear Recoil Energy Spectrum

Rate after integration over WIMP velocity distribution

$$R \sim 0.13 \frac{\text{events}}{\text{kg year}} \left[ \frac{A}{100} \times \frac{\sigma_{WN}}{10^{-38} \text{ cm}^2} \times \frac{\langle v \rangle}{220 \text{ km s}^{-1}} \times \frac{\rho_0}{0.3 \text{ GeV cm}^{-3}} \right]$$

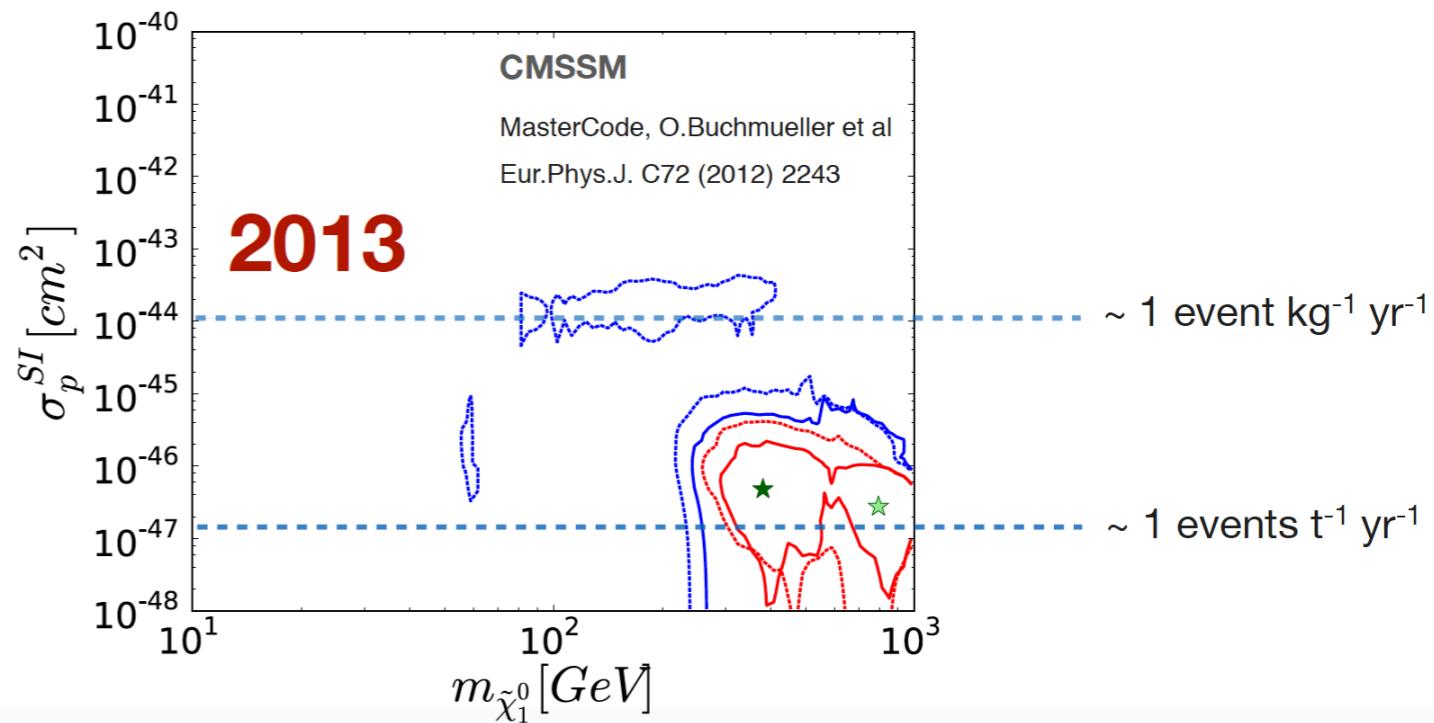

# Detector requirements and signatures

- Requirements for a dark matter detector
  - Large detector mass
  - Low energy threshold ~ sub-keV to few keV's
  - Very low background and/or background discrimination
  - Long term stability

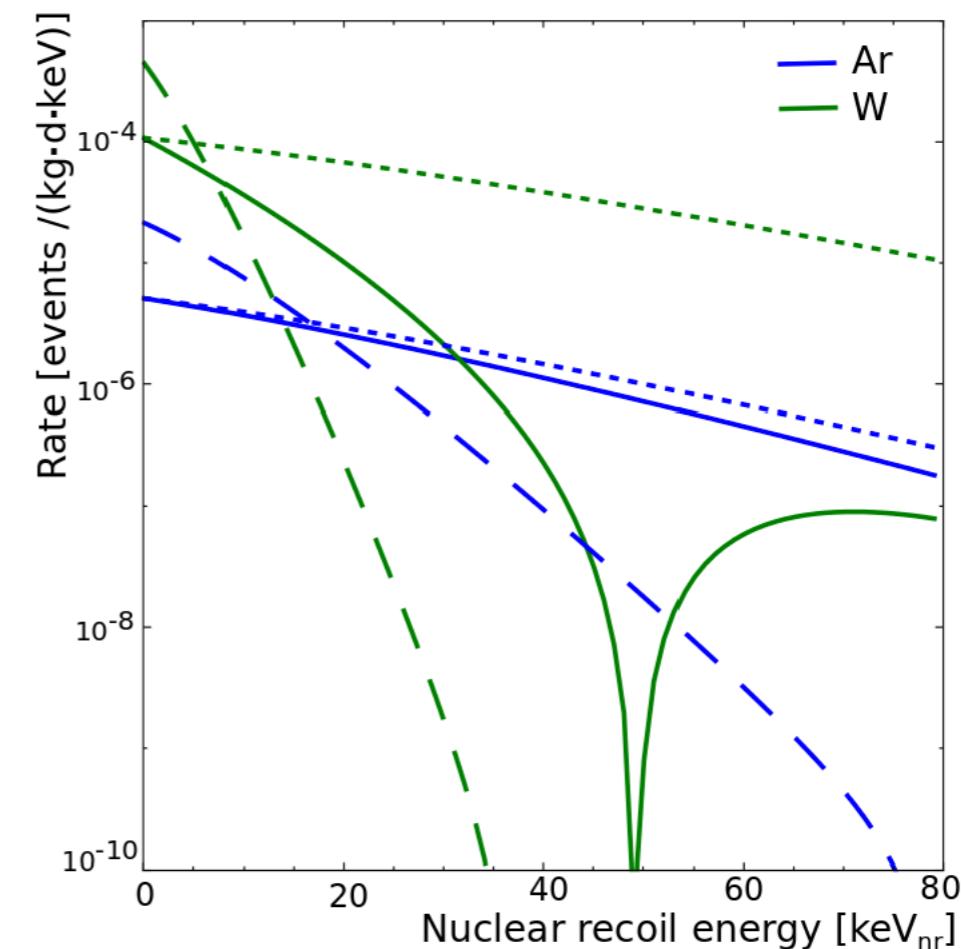

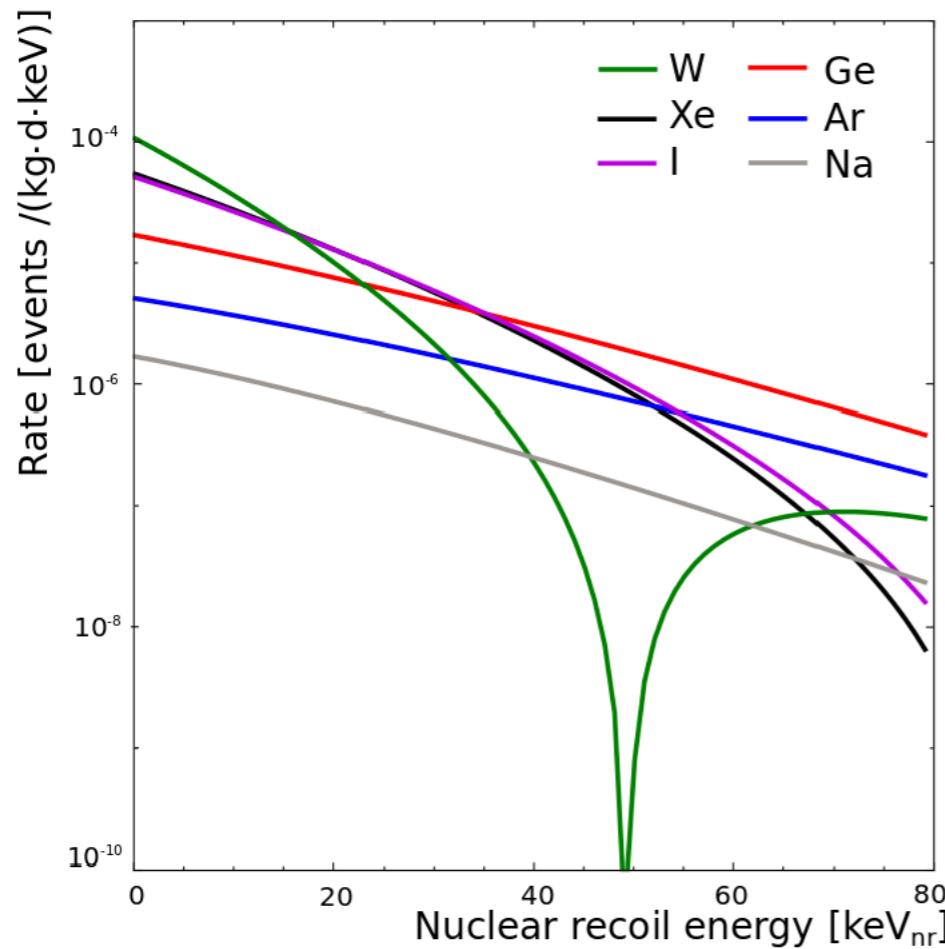

- Possible signatures of dark matter

- Spectral shape of the recoil spectrum
- Annual modulated rate
- Directional dependance

# Signature: spectral shape

$$\frac{dR}{dE}(E) \approx \left( \frac{dR}{dE} \right)_0 F^2(E) \exp\left(-\frac{E}{E_c}\right)$$

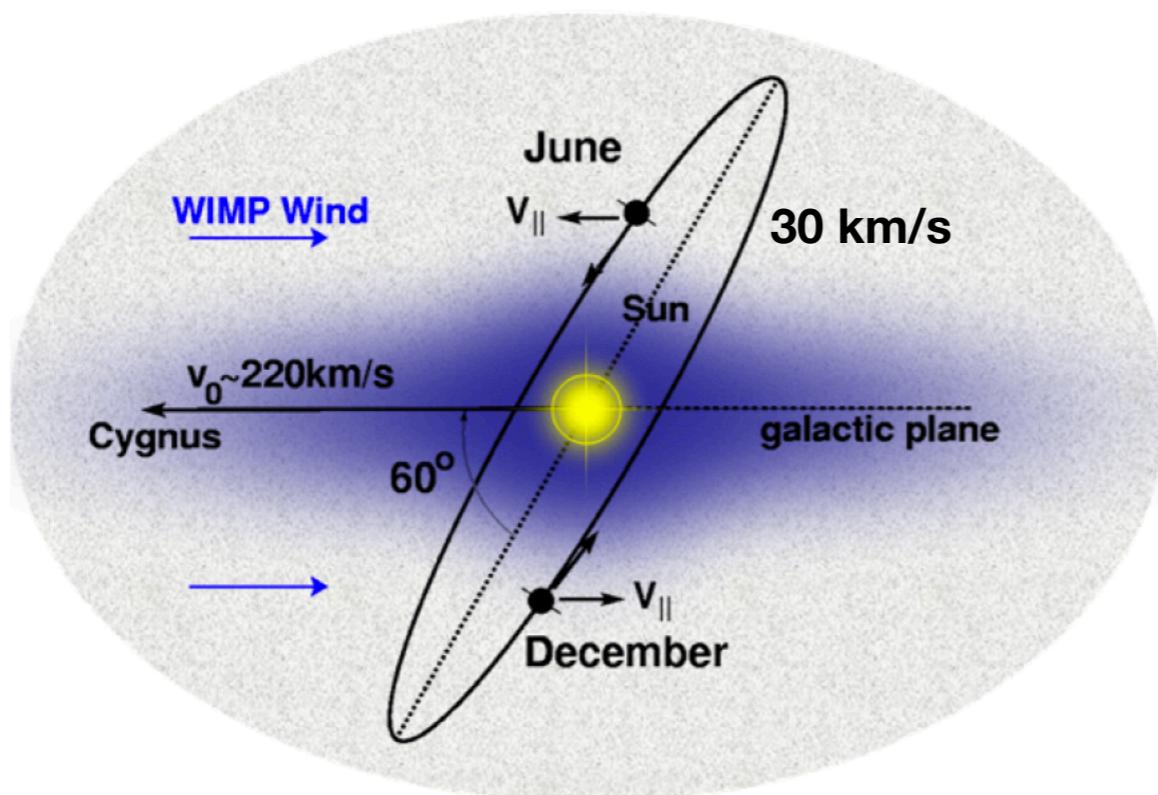

J. Phys. G43 (2016) 1, 013001 & arXiv:1509.08767

Event rates as function of nuclear recoil energy for different target materials **m<sub>W</sub> = 50 GeV**  
Dotted line: no form factor correction  
Dashed line: for a 25 GeV/c<sup>2</sup> WIMP mass

# Signature: annual modulation

$$\frac{dR}{dE}(E, t) \approx S_0(E) + S_m(E) \cdot \cos\left(\frac{2\pi(t - t_0)}{T}\right)$$

- Earth rotation around the Sun
- Relative speed of DM particles larger in summer
- Larger number of nuclear recoils above threshold in summer

# Signature: directionality

$$\frac{dR}{dE d\cos \gamma} \propto \exp \left[ \frac{-[(v_E + v_\odot) \cos \gamma - v_{min}]^2}{v_c^2} \right]$$

$\gamma$ : NR direction relative to the mean direction of solar motion

$v_E$  and  $v_\odot$ : the Earth and Sun motions

$v_c = \sqrt{3/2} v_\odot$ : halo circular velocity

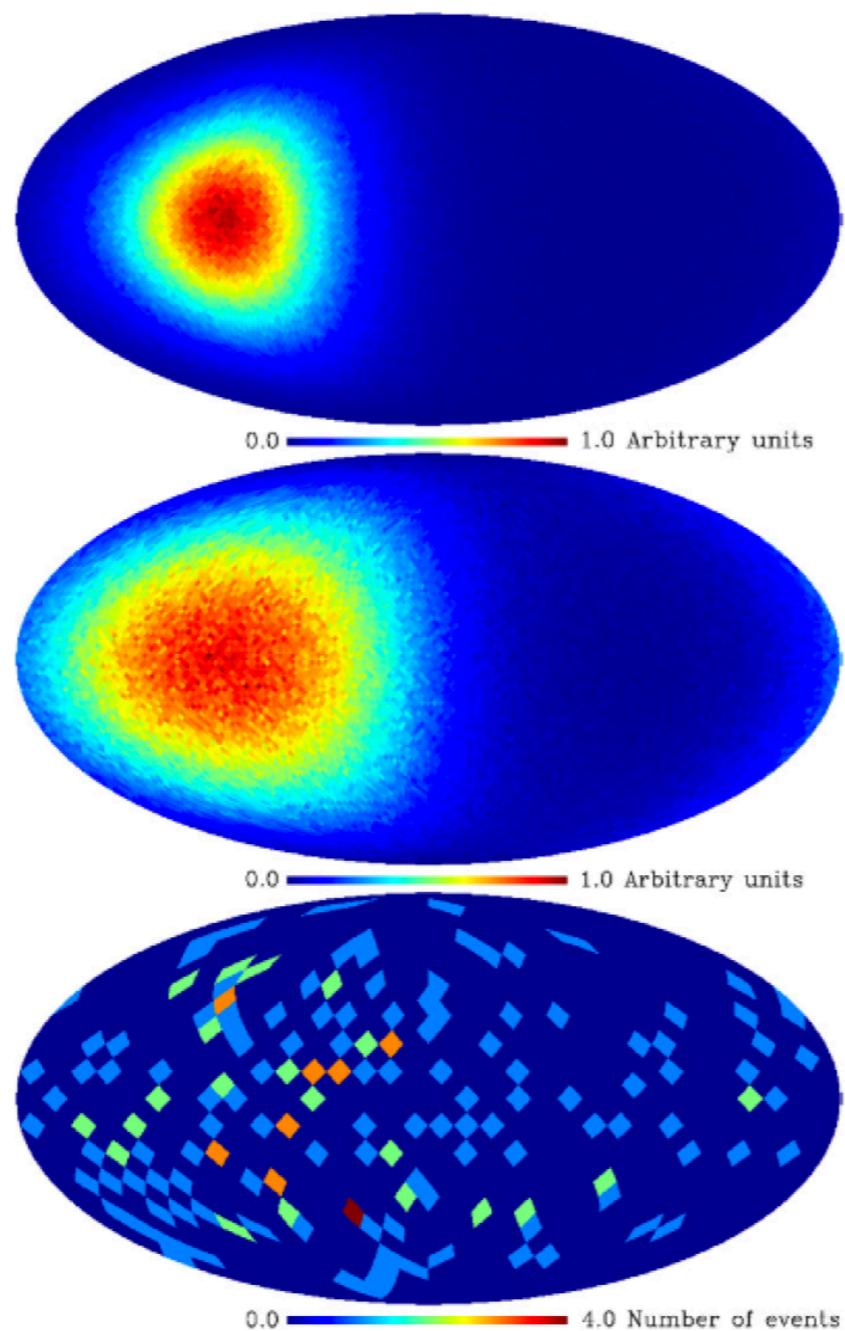

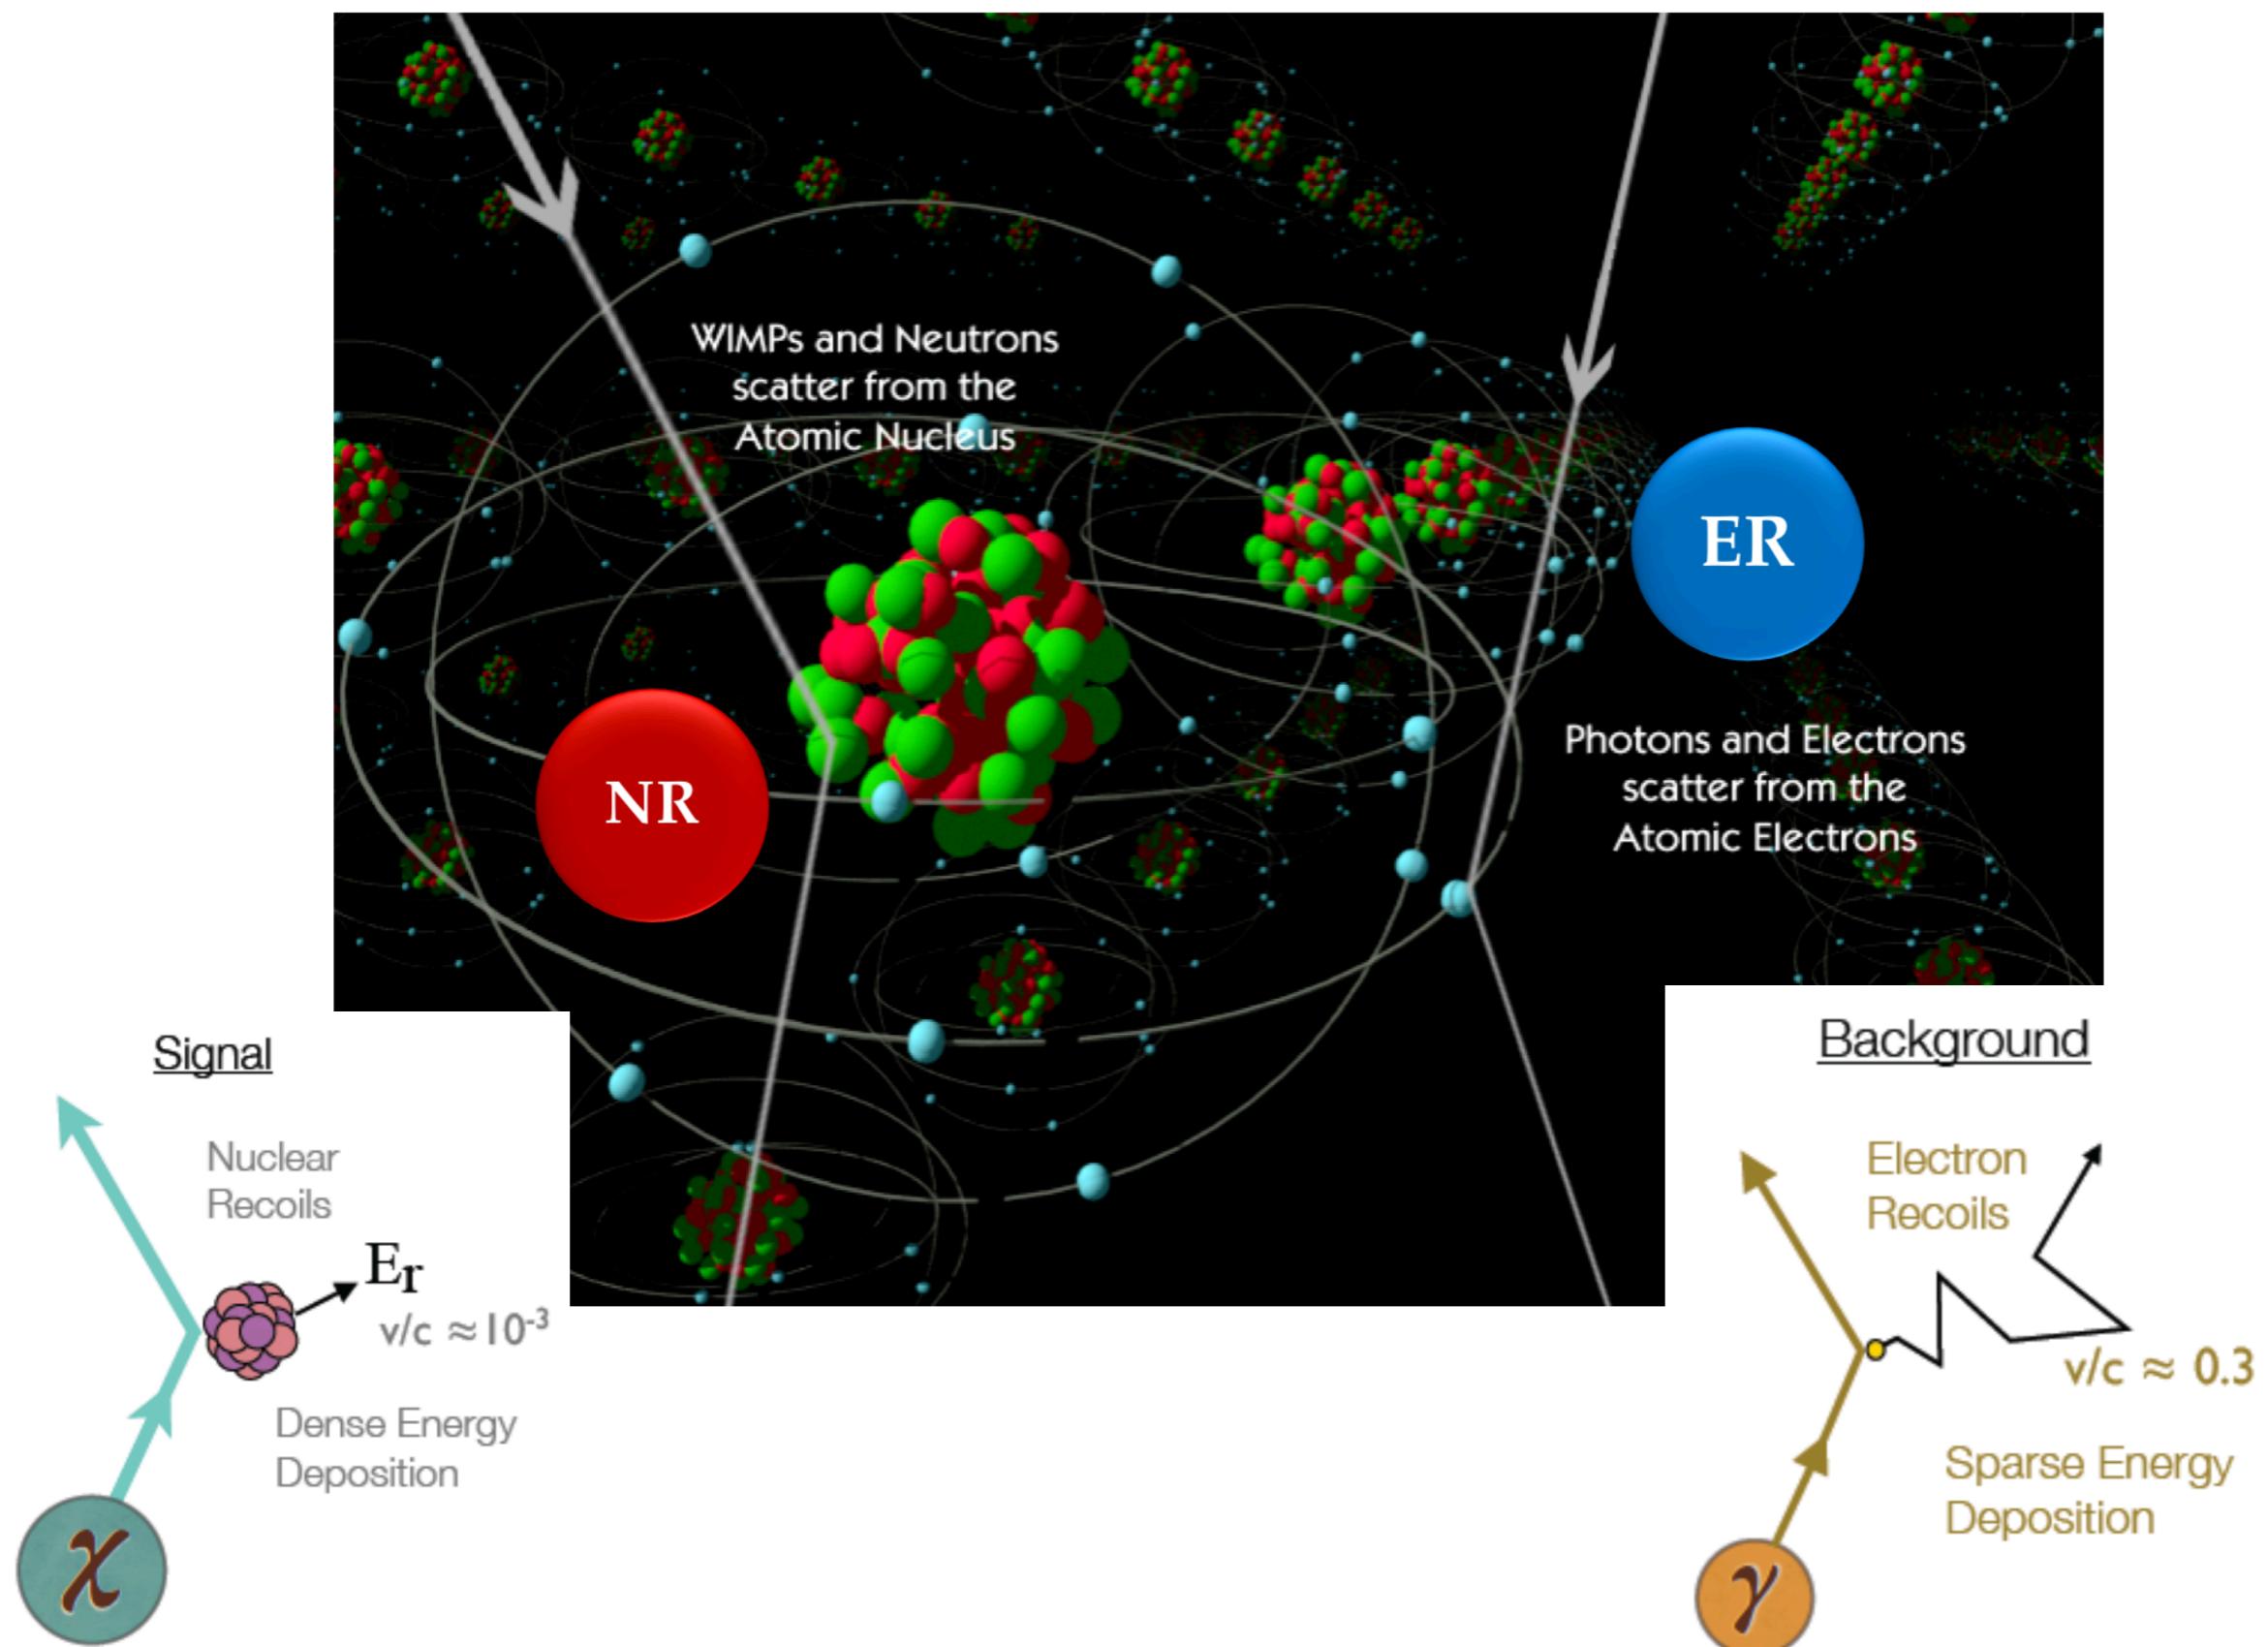

Figure from J. Billard *et al.* 2010

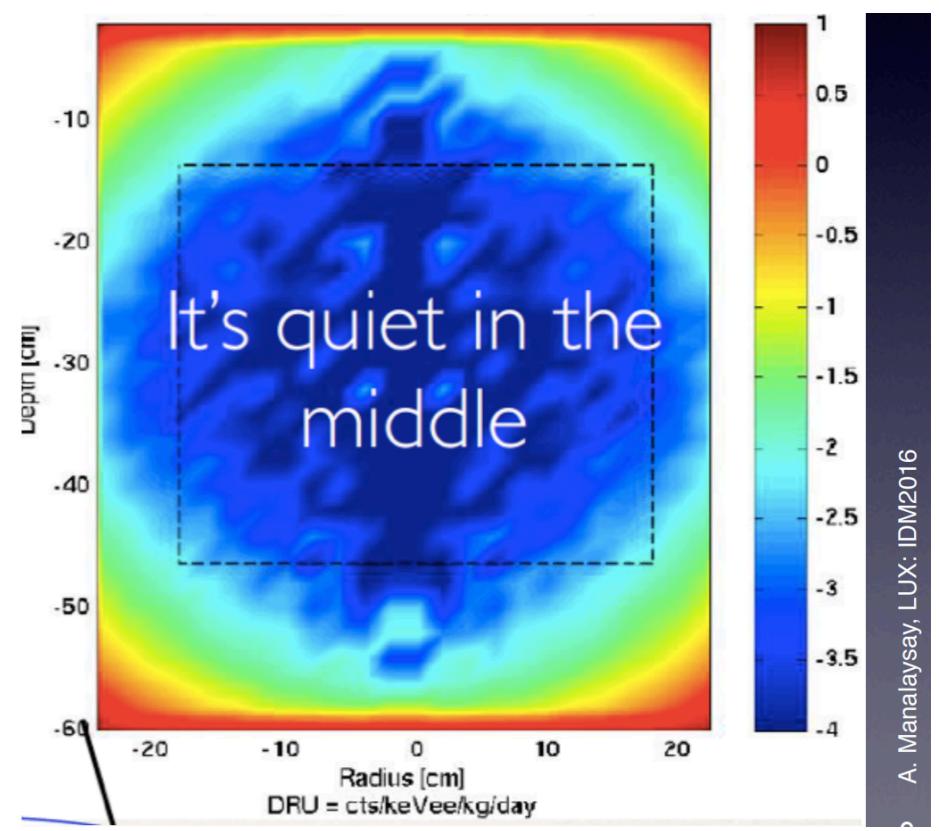

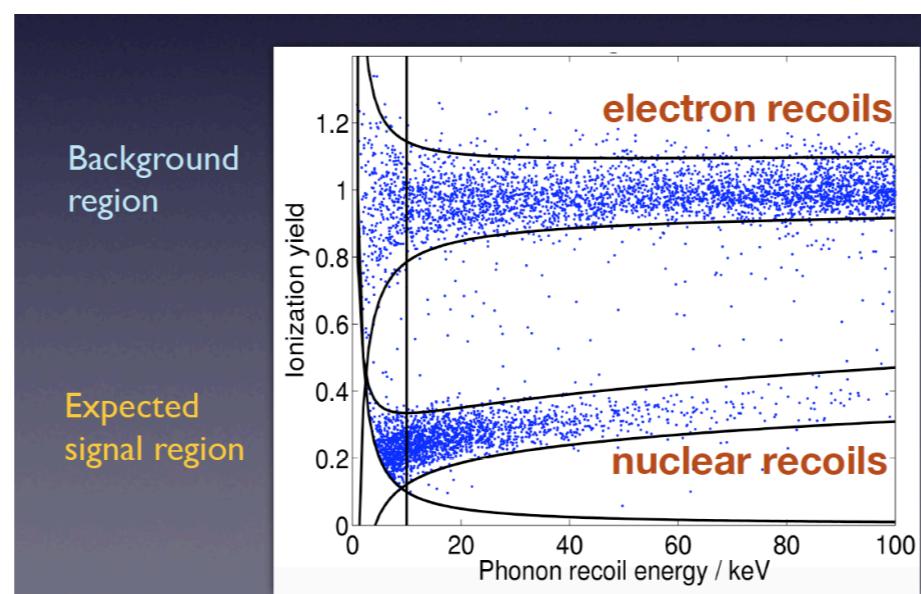

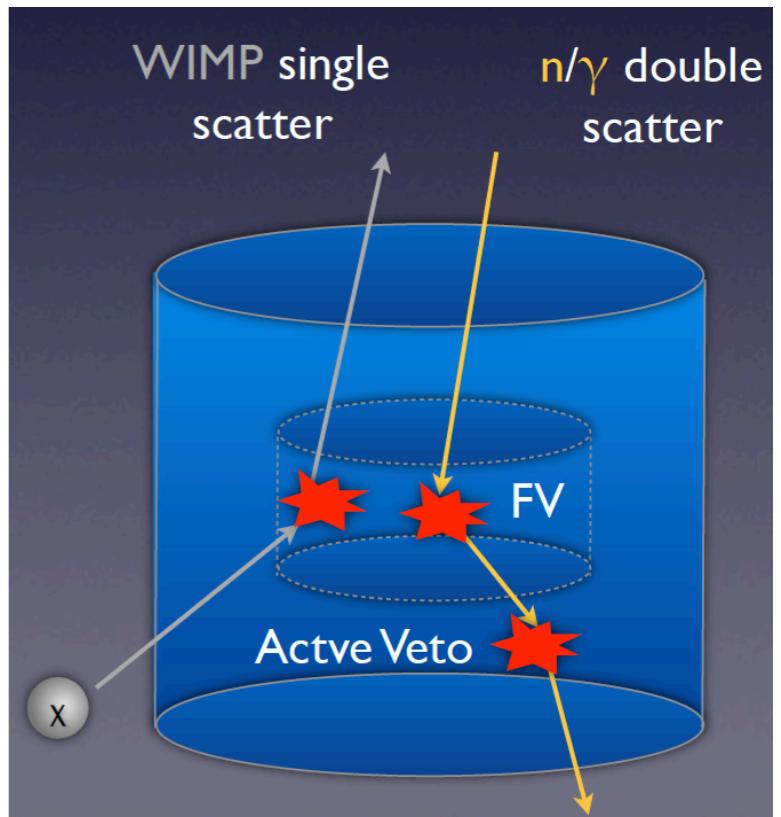

- WIMP flux in the case of an isothermal spherical halo
- WIMP-induced recoil distribution
- A typical simulated measurement:  
100 WIMP recoils and  
100 background events  
(low angular resolution)

# Backgrounds: Electron & Nuclear Recoils

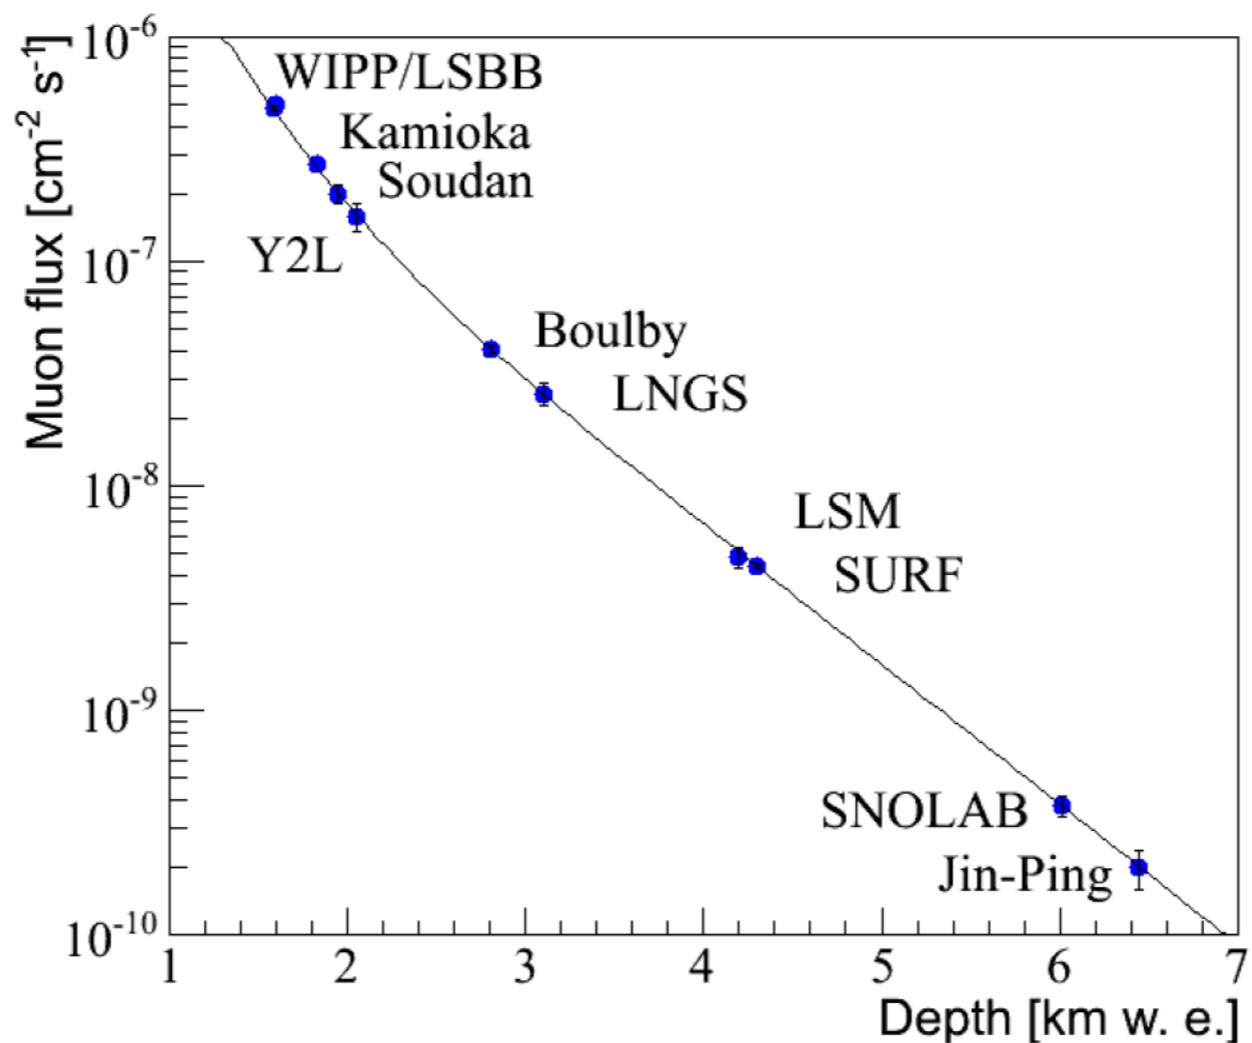

# Backgrounds: external sources

- External  $\gamma$ 's from natural radioactivity:
  - Suppression via self-shielding of the target
  - Material screening and selection
  - Rejection of multiple scatters & discrimination
- External neutrons:  
muon-induced,  $(\alpha, n)$  and from fission reactions
  - Go underground!
  - Shield: passive (polyethylene) or active (water/scintillator vetoes)
  - material selection for low U and Th contaminations
- Neutrinos:  
from the Sun, atmospheric and from supernovae
  - Elastic neutrino-electron scattering
  - Coherent neutrino-nucleus scattering

# Underground laboratories

- WIPP in USA (DMTPC)
- LSBB in France (SIMPLE)
- Kamioka in Japan (XMASS, NEWAGE)
- Soudan in USA (SuperCDMS, GoGeNT)
- Y2L in Corea (KIMS)
- Boulby in UK (DRIFT, ZEPLIN)
- LNGS in Italy (XENON, DAMA, Cresst, DarkSide)
- LSM in France (Edelweiss, MIMAC)
- SURF in USA (LUX)
- SNOLAB in Canada (DEAP/CLEAN, PICASSO, COUPP)
- Jin-Ping in China (PandaX, CDEX)

# Underground laboratories

# Backgrounds: internal and surface sources

---

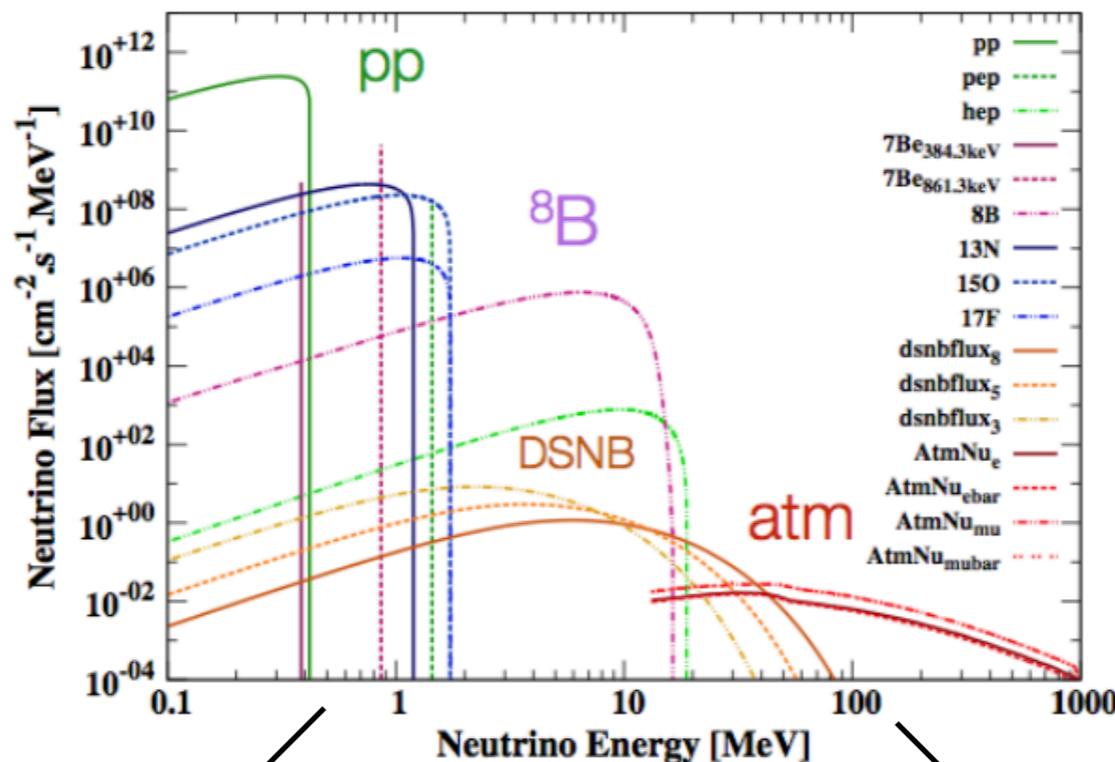

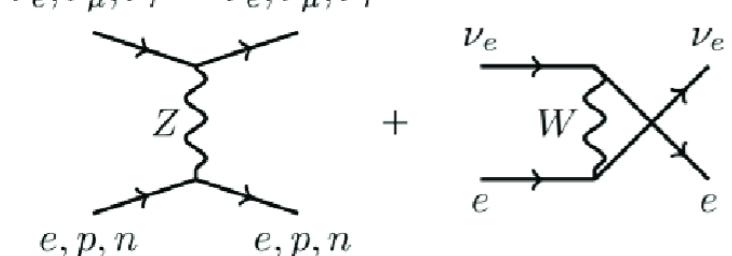

- Internal contamination in liquids:

- $^{85}\text{Kr}$ : removal by cryogenic distillation/chromatography/centrifuges
- Rn: removal using activated carbon, distillation, dust removal
- Argon:  $^{39}\text{Ar}$  (565 keV endpoint, 1 Bq/kg),  $^{42}\text{Ar}$
- Xenon:  $^{136}\text{Xe}$   $\beta\beta$  decay ( $T_{1/2} = 2.2 \times 10^{21}$  y) *long lifetime!*

- Surface background in solids:

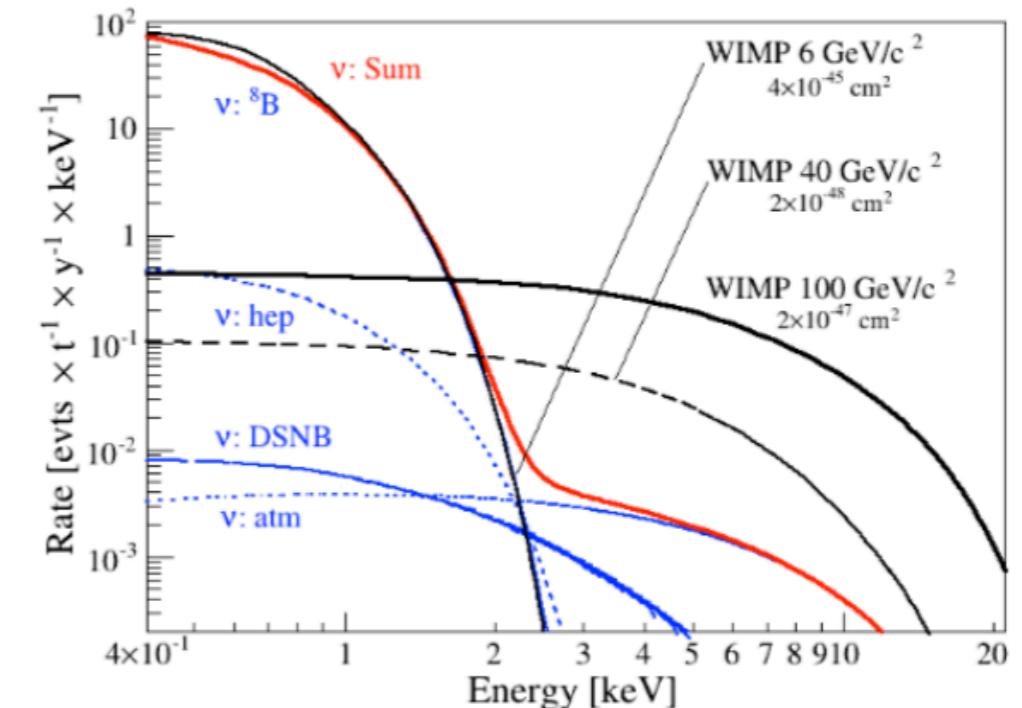

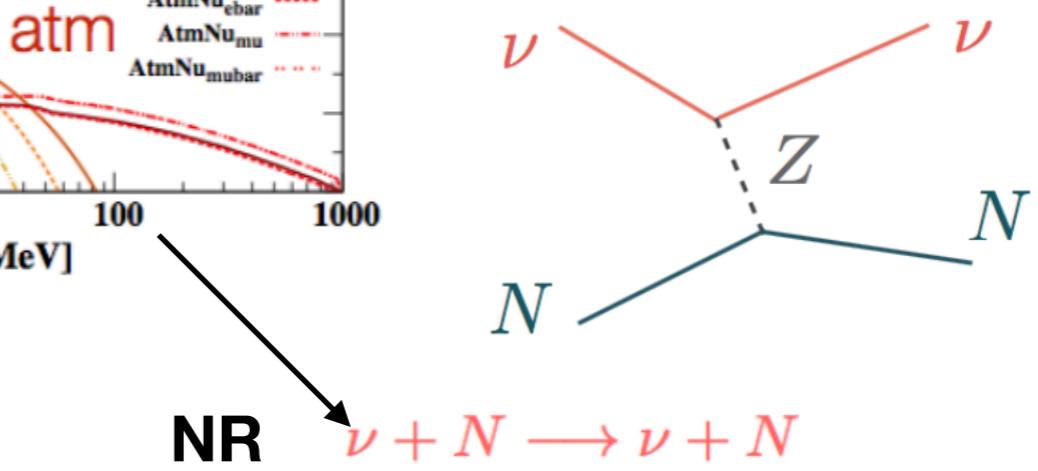

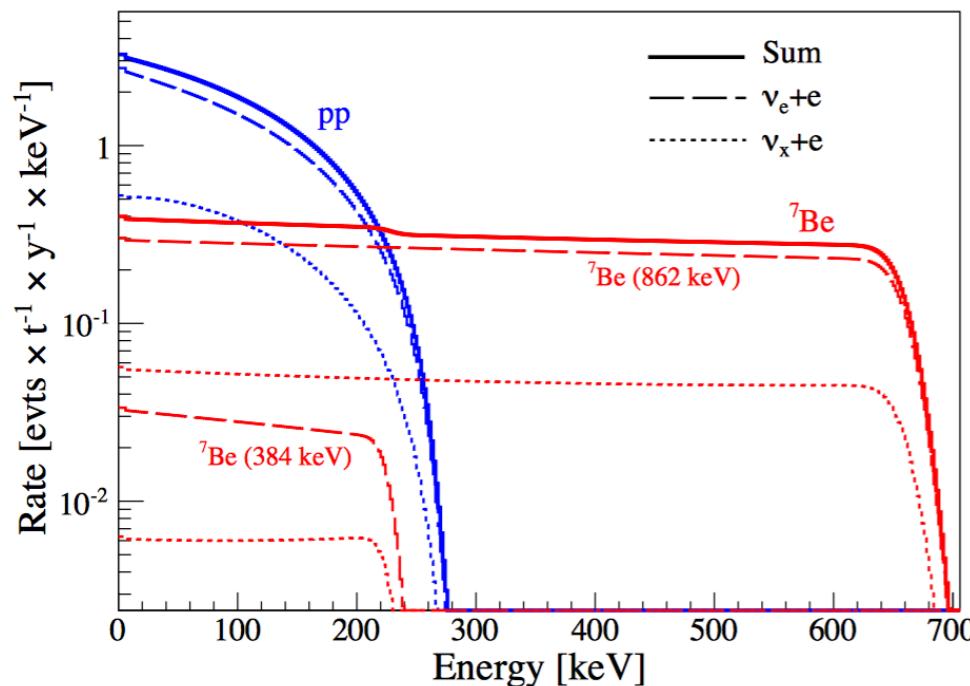

- Germanium detectors or solid scintillators grown out of high purity powders or melts → low intrinsic background
- Cosmic activation
- Surface events from  $\alpha$  or  $\beta$ -decays

# The ultimate background from neutrinos

F. Ruppin et al., 1408.

**ER**

LB et al., JCAP01 (2014) 044

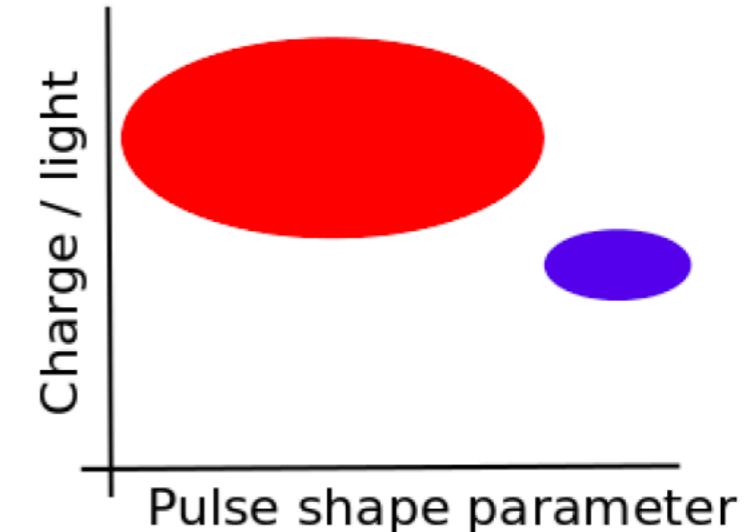

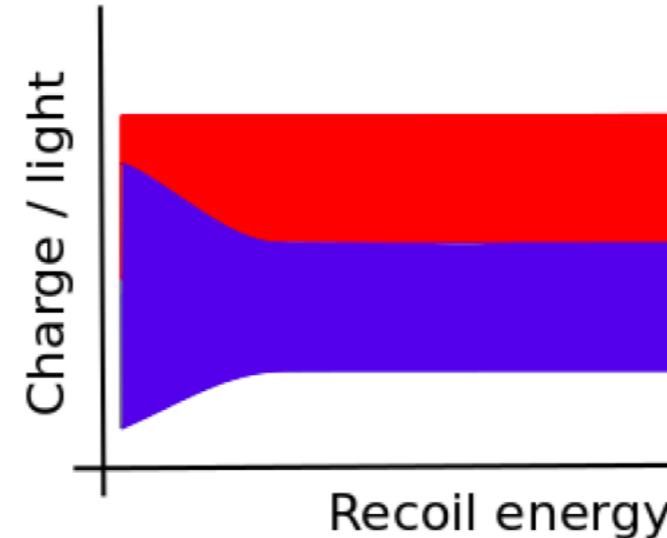

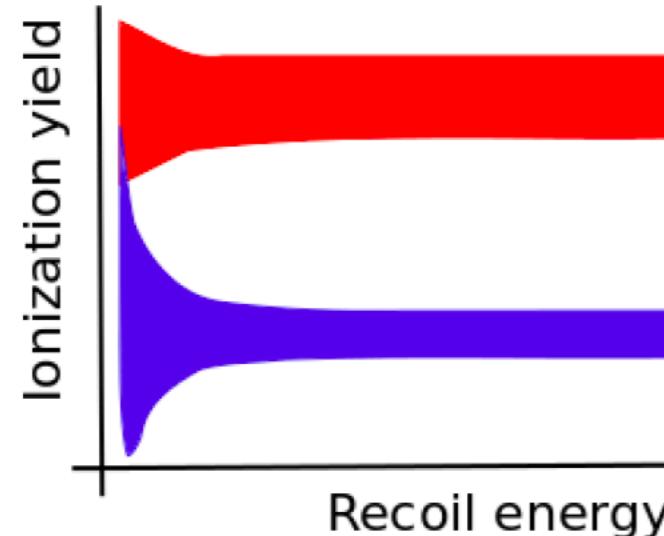

# Detector Calibration

---

Purposes of detector calibration:

- **Data stability:**  
monitoring of detector parameters (amplification of signals, slow control parameters, ..) and of the related electronics
- **Determination of energy scale:**  
detector signals are photoelectrons, charges or heat  
→ need to convert to  $\text{keV}_{nr}$
- **Determination of signal and background regions:**  
description of nuclear and electronic recoil regions

# Detector Calibration: Signal & Background

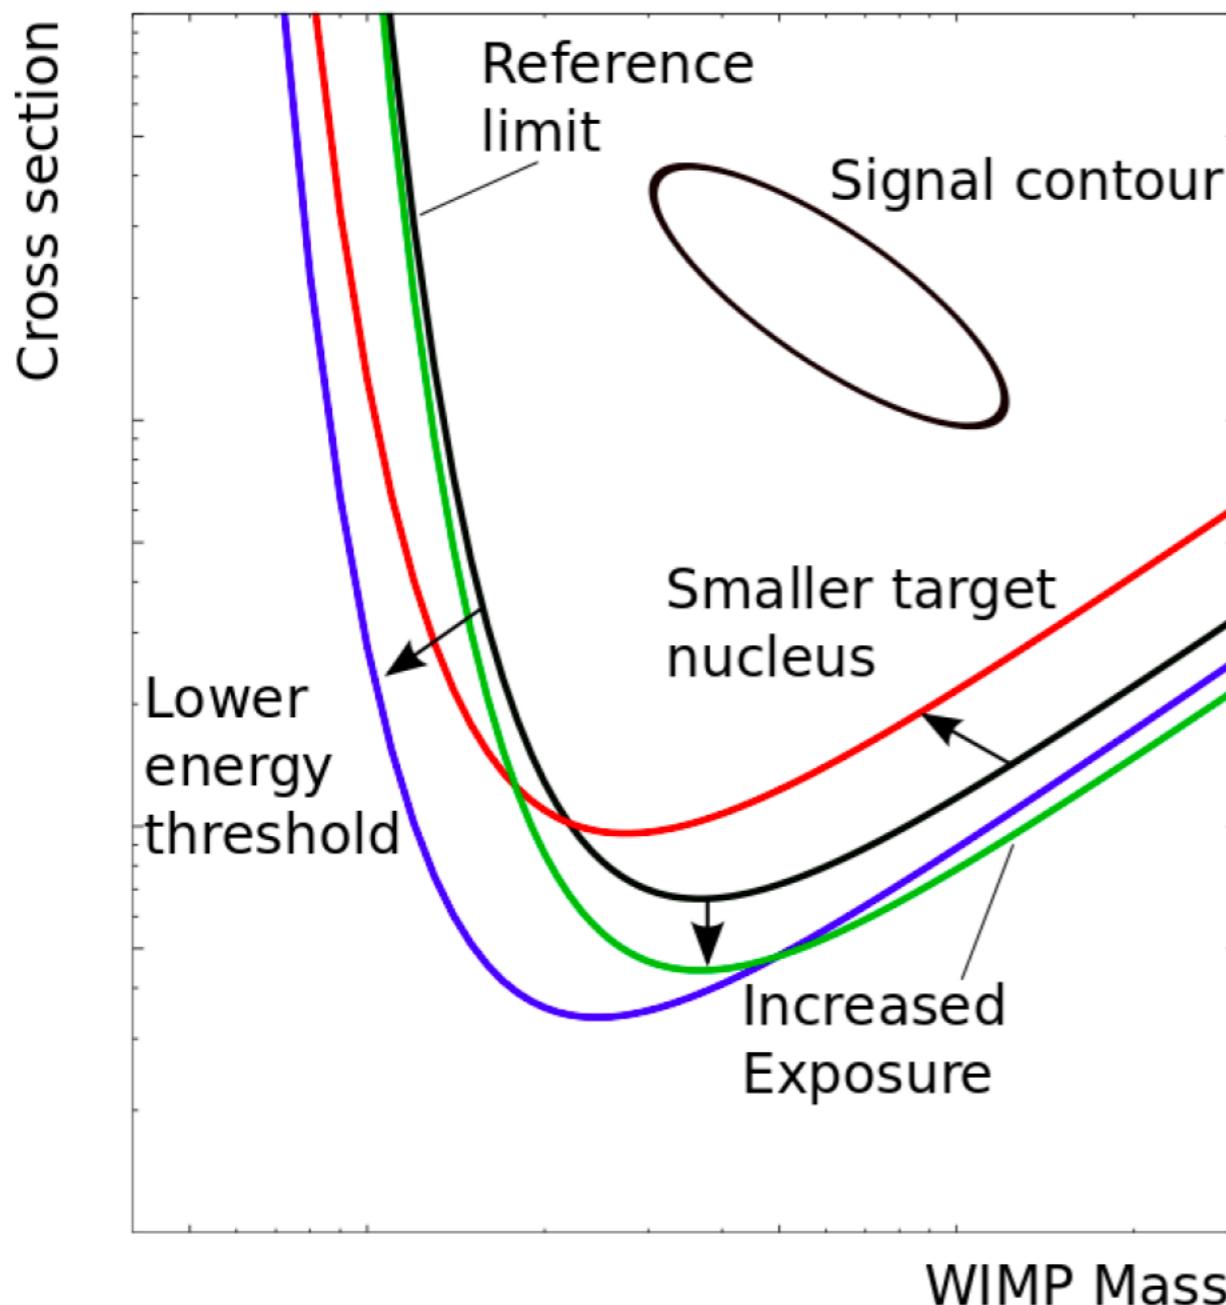

- Discrimination in a [cryogenic germanium detector](#) (left)  
No surface events included!
- Discrimination in a [liquid xenon detector](#) (middle)
- Discrimination in a [liquid argon detector](#) (right)  
Two parameters available for discrimination

# Sensitivity plot in direct DM experiments

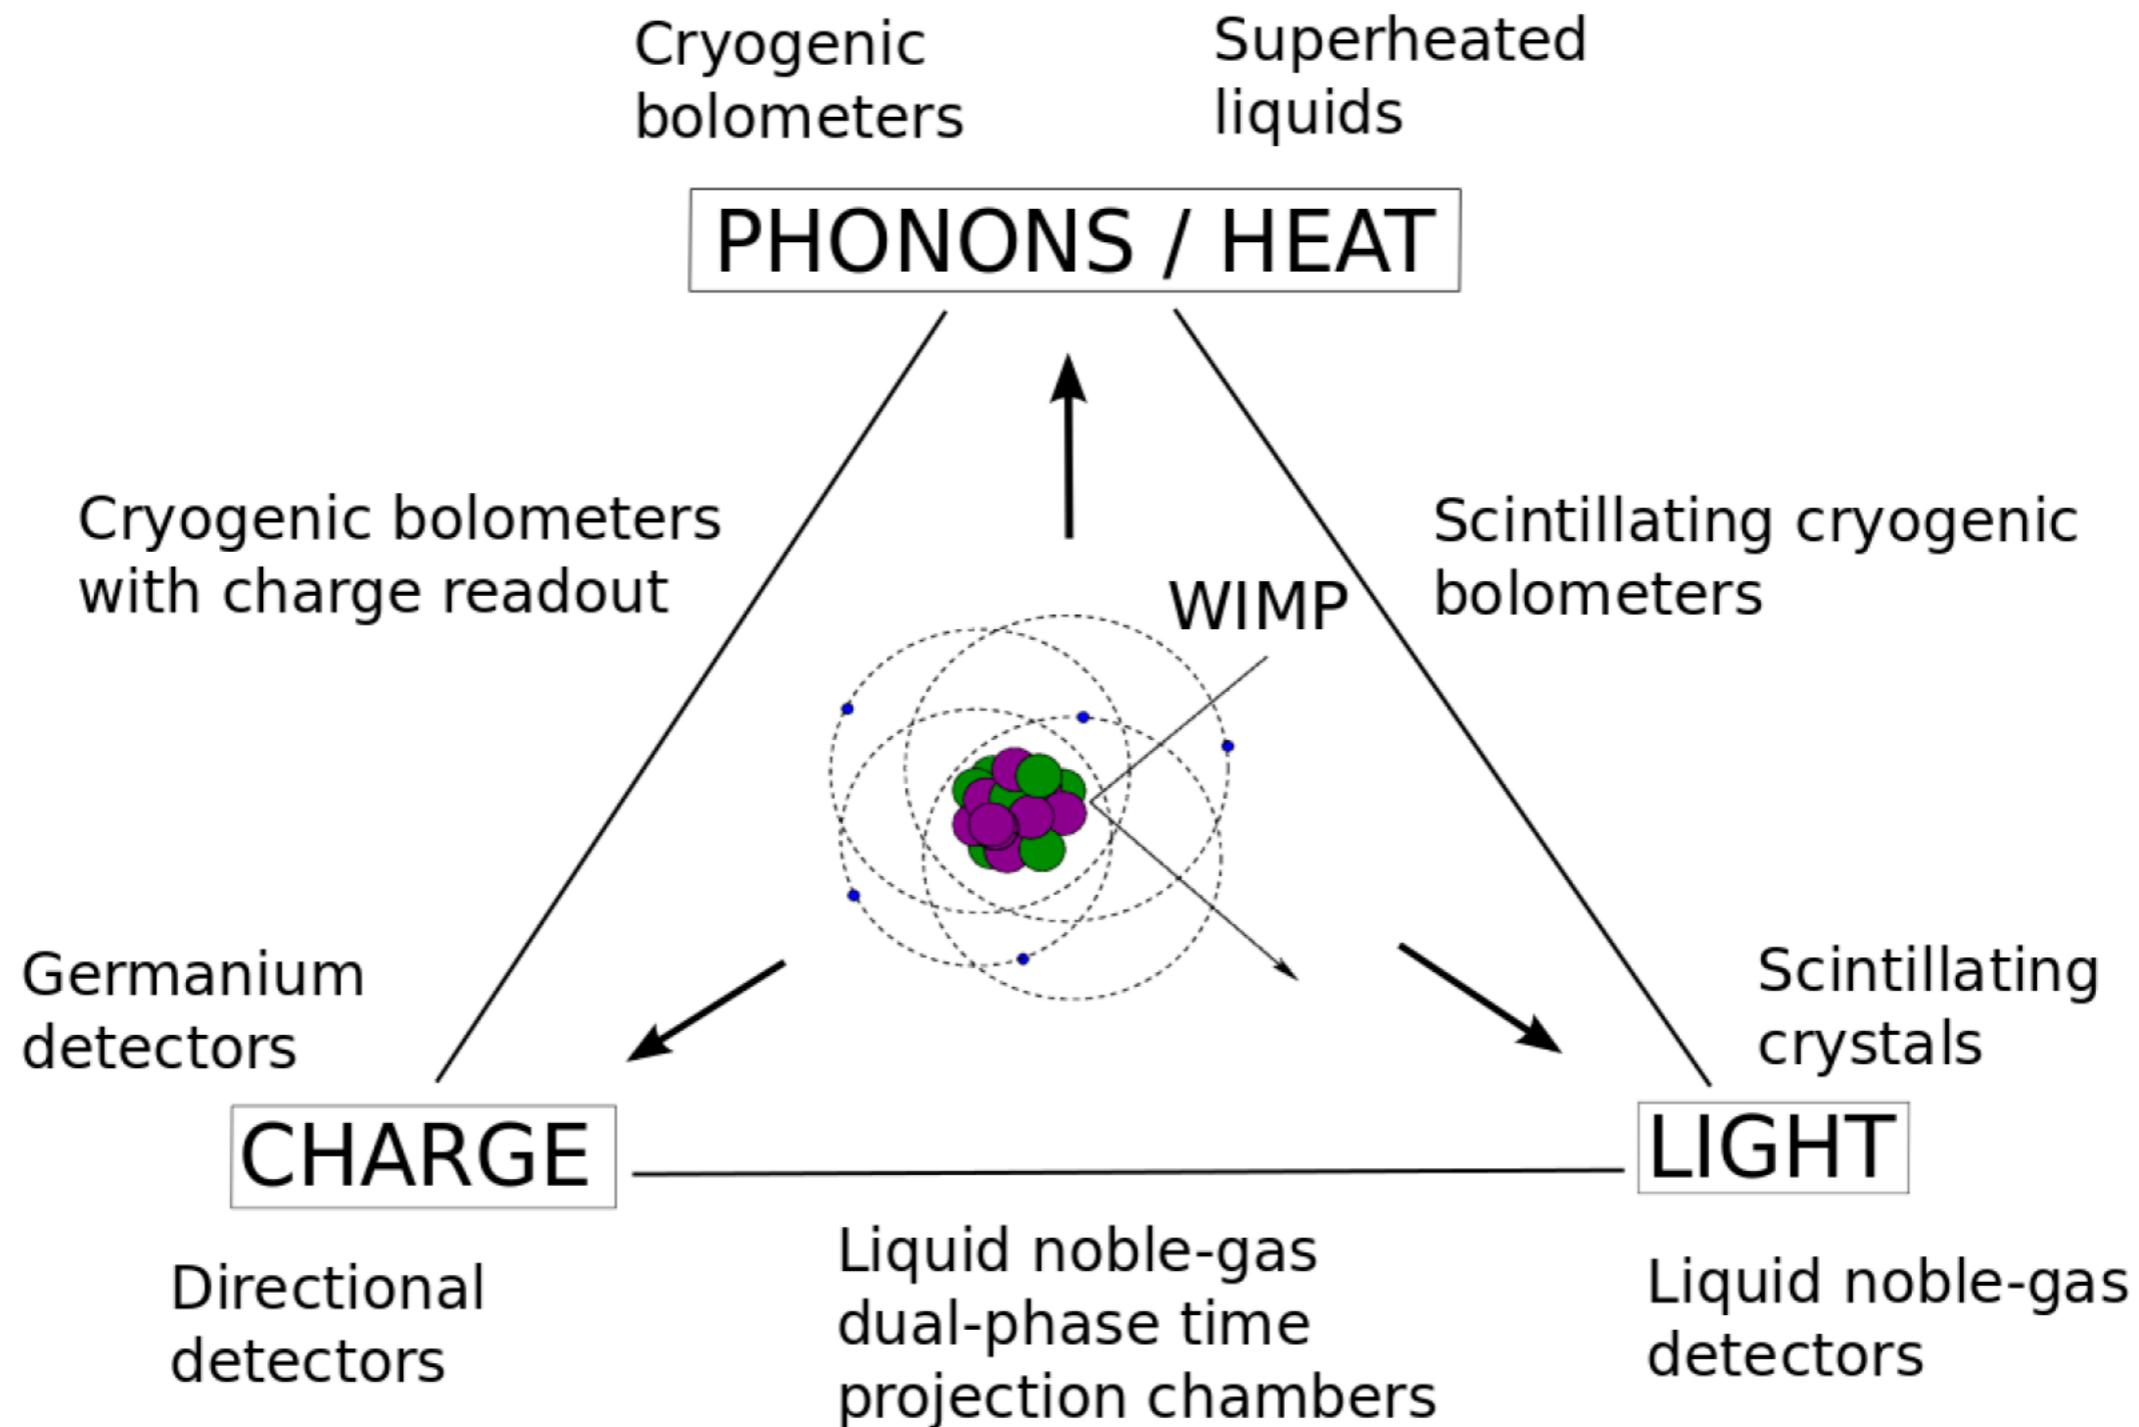

→ Statistical significance of signal over expected background?

J. Phys. G43 (2016) 1, 013001 & arXiv:1509.08767

- Positive signal
  - Region in  $\sigma_\chi$  versus  $m_\chi$
- Zero signal
  - Exclusion of a parameter region
- Low WIMP masses:  
detector threshold matters
- Minimum of the curve:  
depends on target nuclei
- High WIMP masses:  
exposure matters  $\epsilon = m \times t$

# Direct detection Techniques

J. Phys. G43 (2016) 1, 013001 & arXiv:1509.08767

# Direct Detection Techniques

- Liquid argon
- Liquid xenon
- Directional detectors
- Low-threshold
- Bubble chambers
- Cryogenic bolometers
- Scintillating crystals

# Competitive field, rapid progress

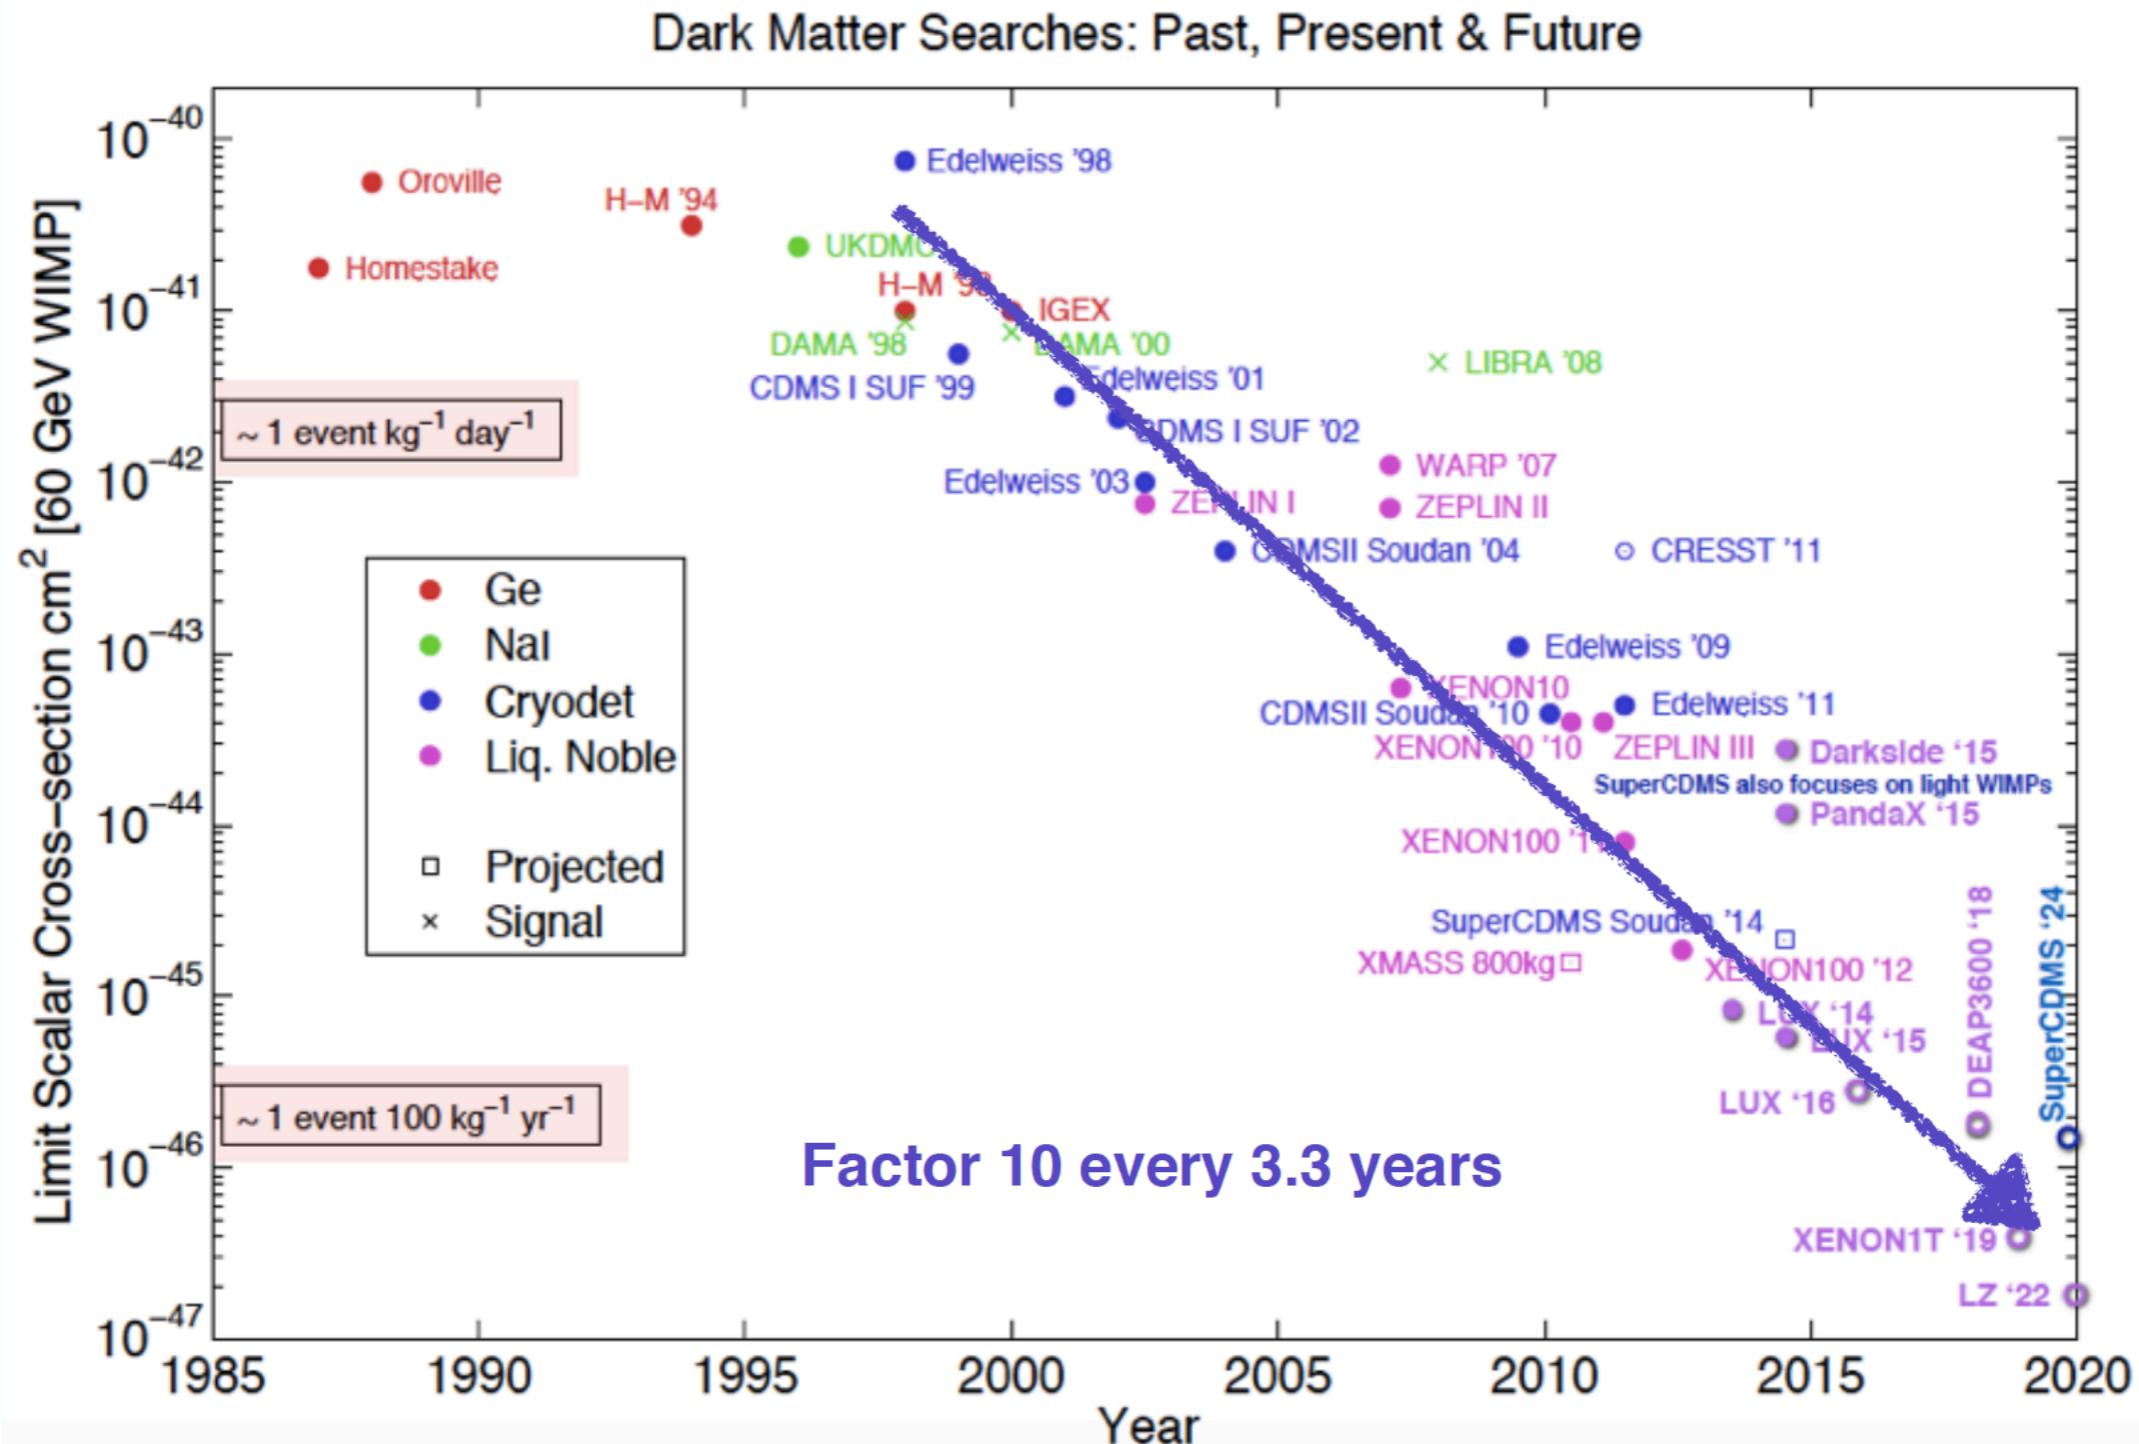

**detector sensitivity improved by ~5 orders of magnitude in the last 20 years**

# Competitive field, rapid progress

**detector sensitivity improved by ~5 orders of magnitude in the last 20 years**

# Competitive field, rapid progress

**detector sensitivity improved by ~5 orders of magnitude in the last 20 years**

# Two main lines of improvements (+ others)

- **Liquid Noble targets**

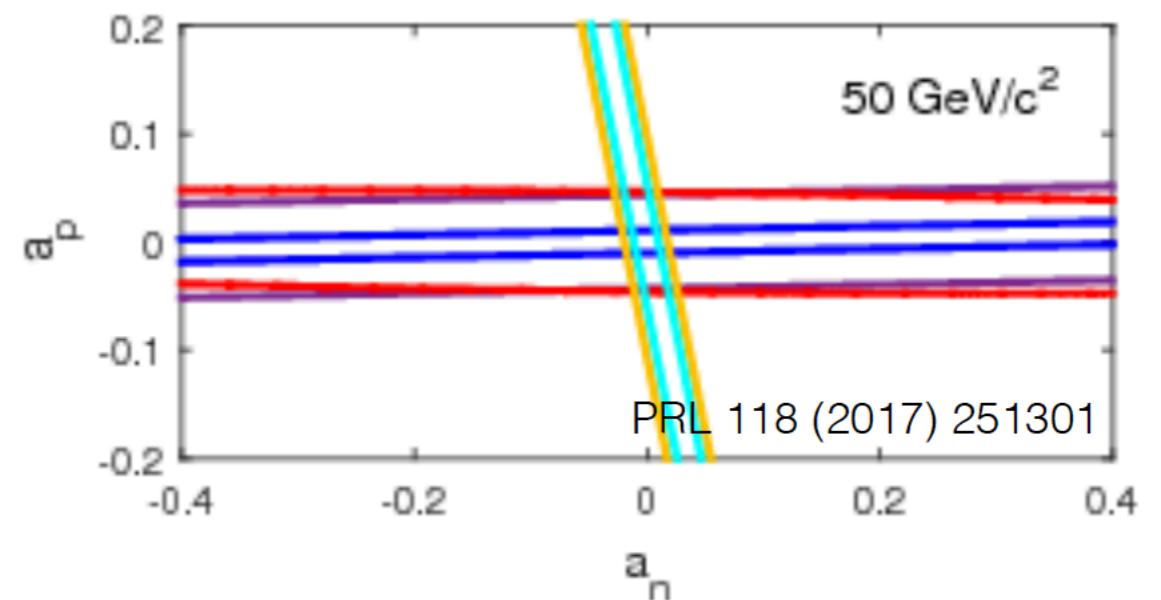

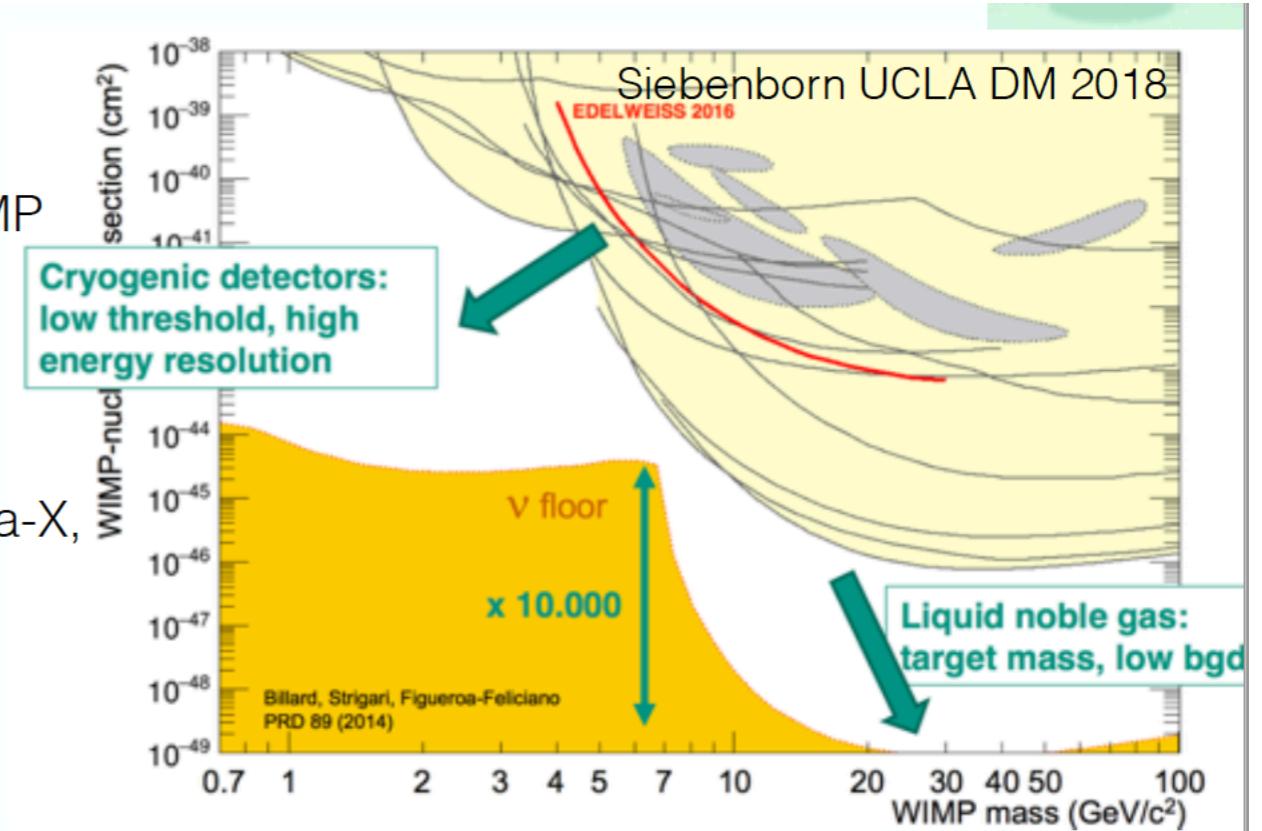

- Largest and most sensitive over the widest WIMP range
- 5 GeV-1 TeV WIMP masses probed
- Darkside, DARWIN, DEAP3600, LUX, LZ, Panda-X, XENON1T, XENONnT

- **Cryogenic crystal targets**

- Oldest technology, with new innovations
- 1-10 GeV WIMP masses probed
- CRESST, EDELWEISS, SuperCDMS,

- **Alternate targets with unique properties**

- NaI crystals, bubble chambers
- ANAIS, COSINE, DAMA/LIBRA, SABRE, PICO

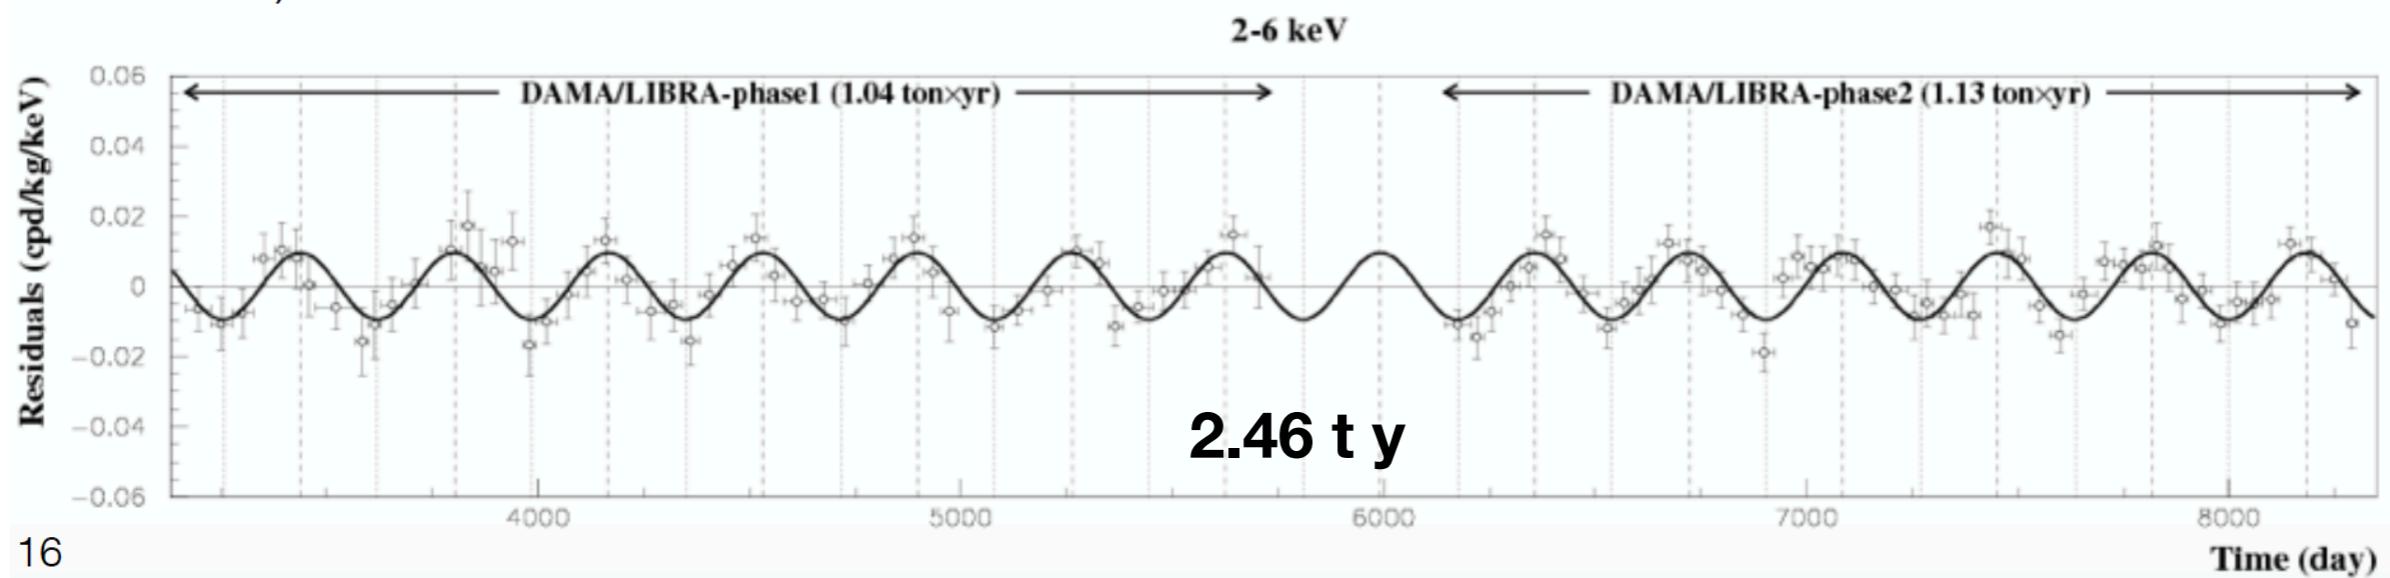

# Scintillating crystals

---

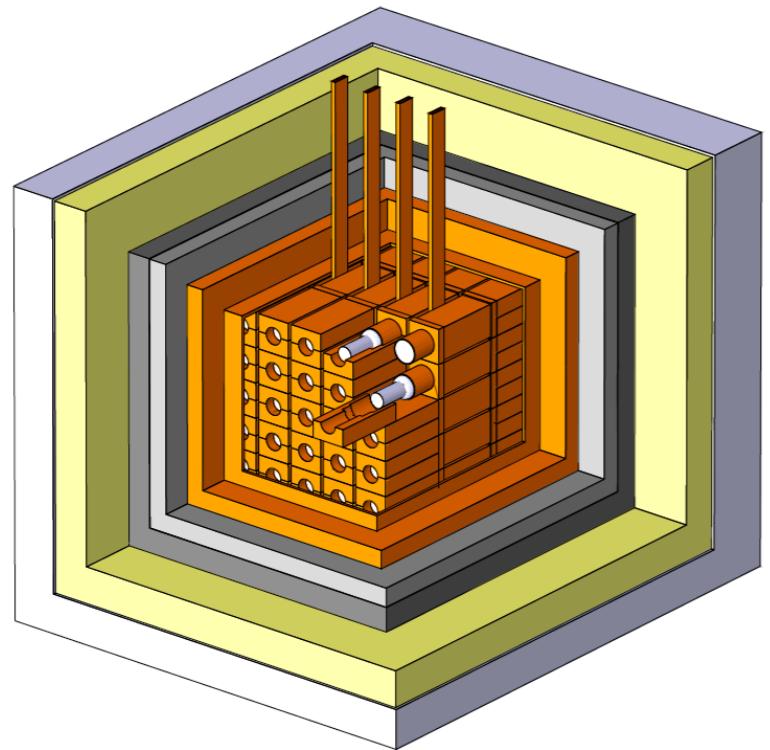

- Mostly NaI (Tl) and CsI (Tl) used in dark matter searches
- Arrays of several crystals at room temperature
  - simple operation, important for long-term stability
- No particle discrimination
  - Low radioactivity of the target material
  - Rejection of multiple scatters in different crystals

# DAMA-LIBRA new results

- DAMA and DAMA/LIBRA phase 1
  - 250-kg high-purity NaI(Tl) array collected data for 14 solar cycles
  - observed  $\sim 0.01$  cpd/kg/keV modulation in 2 - 6 keV energy range
  - over  $9\sigma$  stat. significant; WIMP signal interpretation in tension with other experiments
- DAMA/LIBRA phase 2 arXiv:1805.10486
  - 250-kg high-purity NaI(Tl) array collected data for 6 solar cycles
  - 2-6 keV range combined now gives  $12.9\sigma$  stat. significant
  - Modulation clearly evident in lowest energy bins now too (1-3 keV)

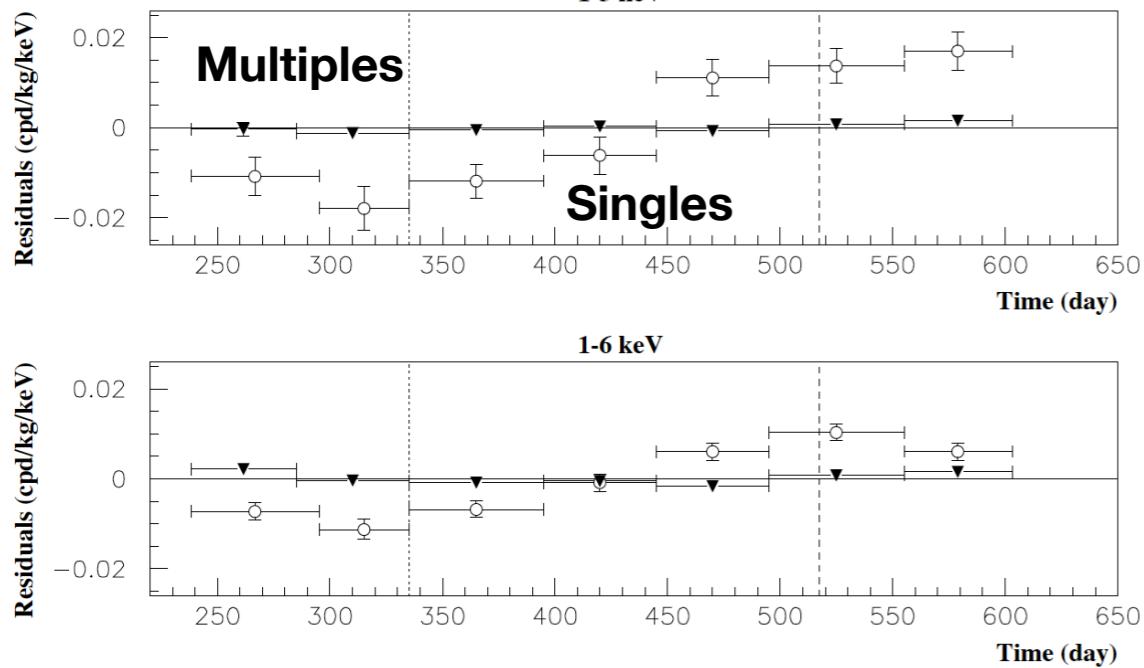

# DAMA-LIBRA new results

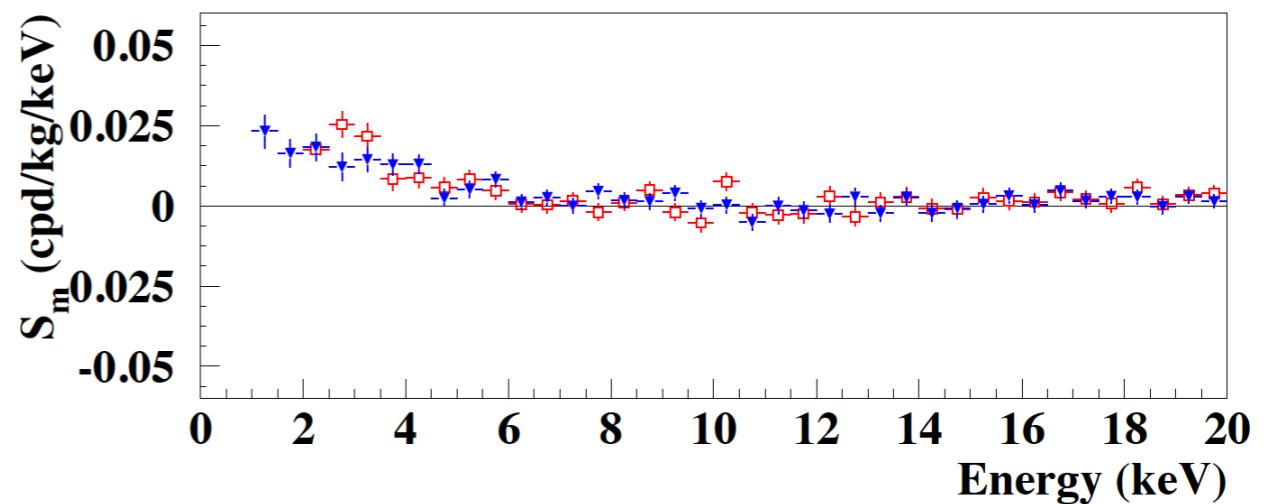

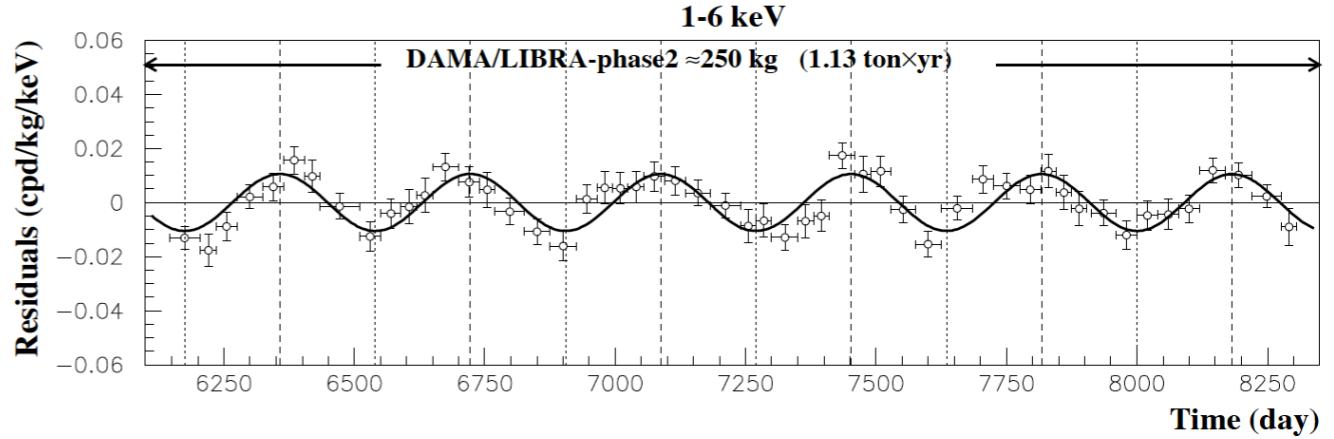

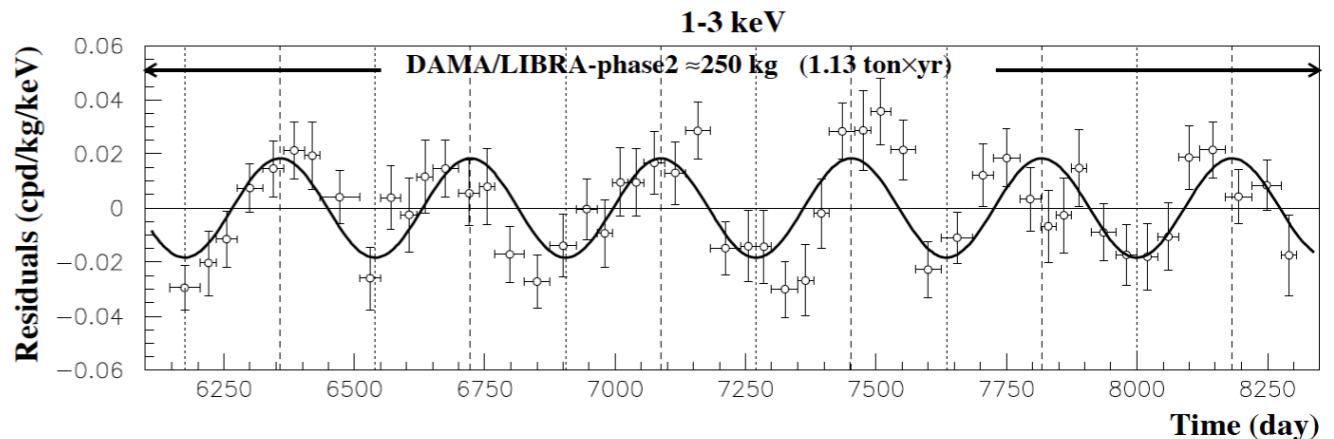

a)

b)

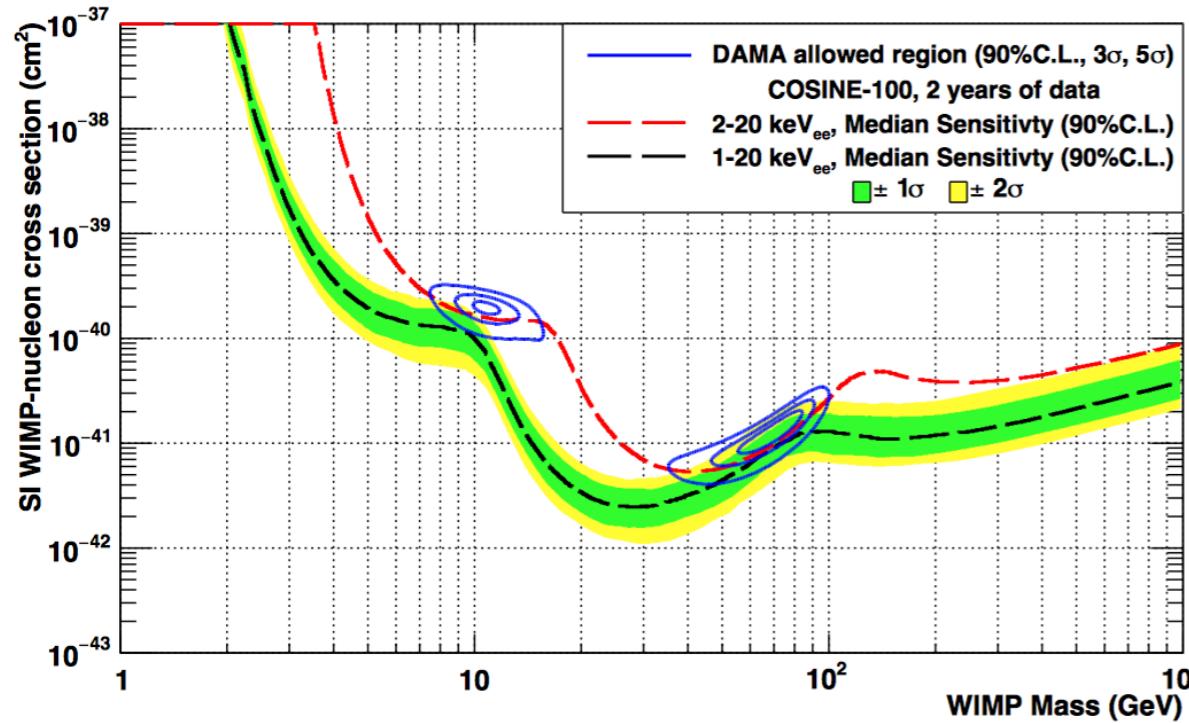

**Very hard to attribute it to  
neutrons, muons, or worst ... neutrinos !!!**

# Future in NaI detectors

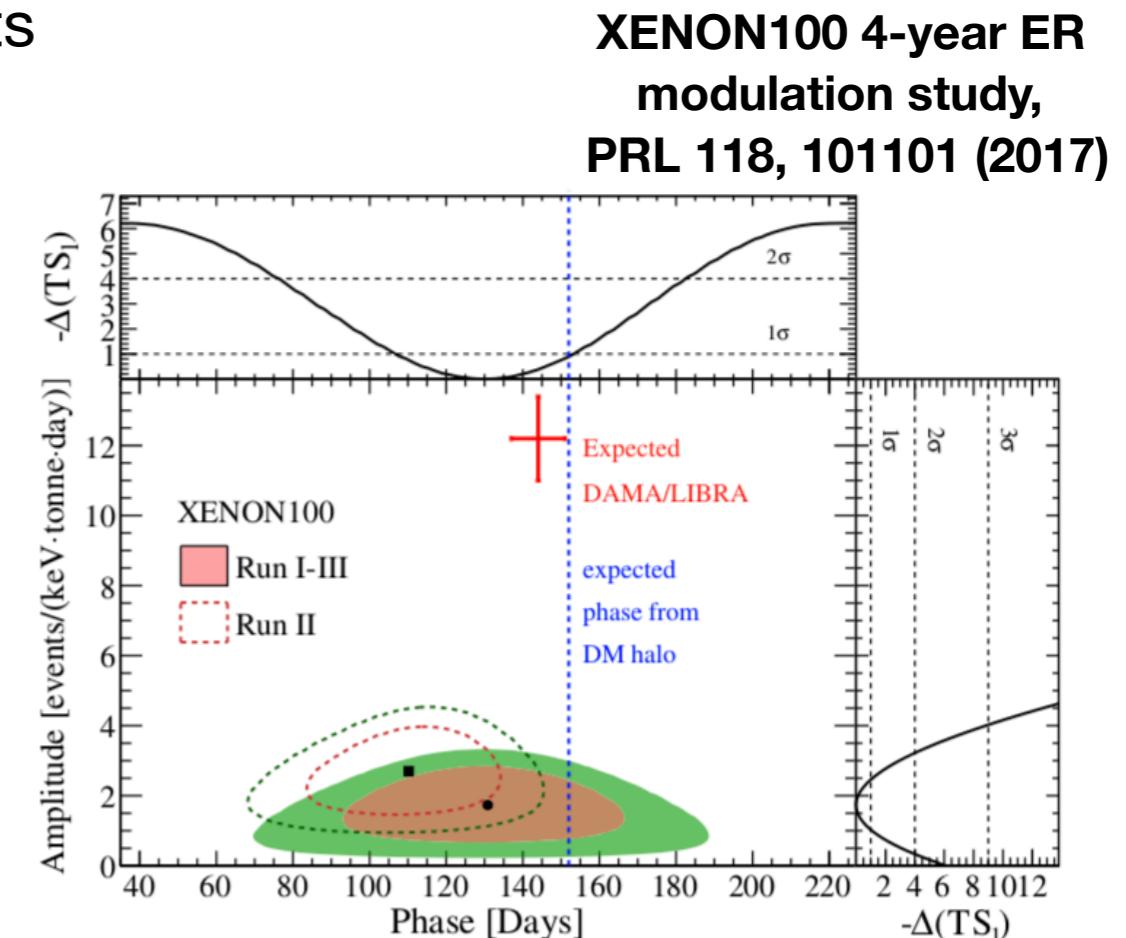

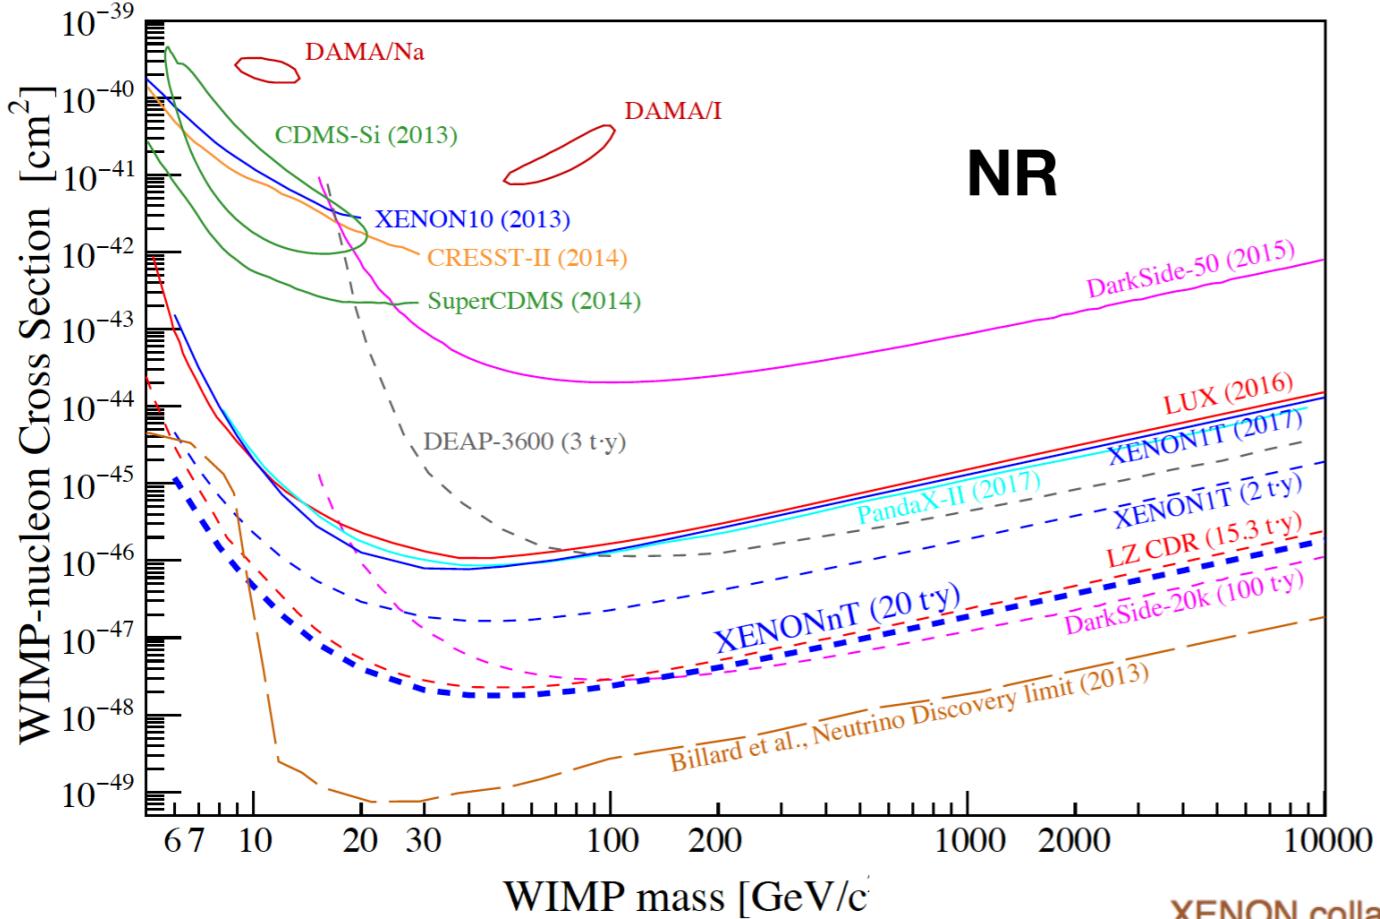

- COSINE100 running since September 2016
- ANAIS 112 started operations in August 2017 and will have 3  $\sigma$  significance after 5 years

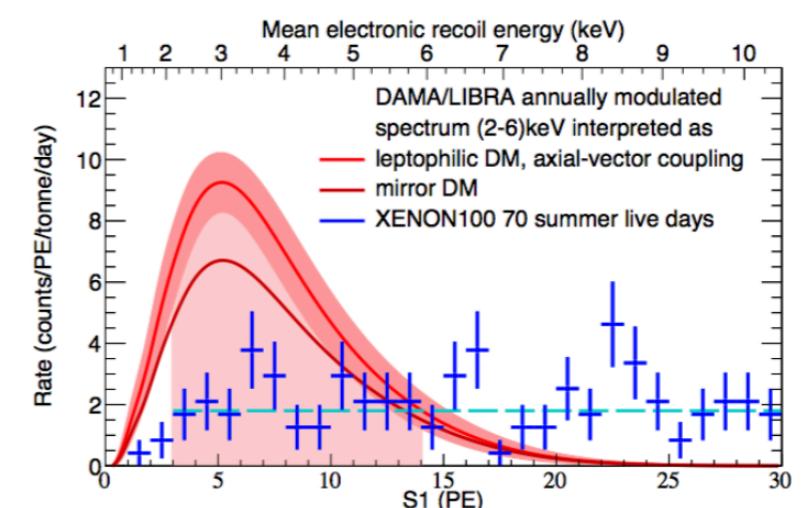

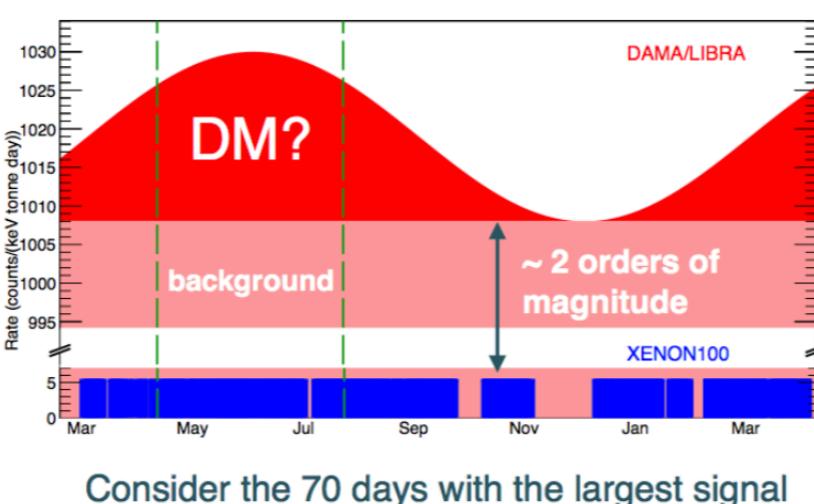

- SABRE 5 kg proof of principle starts this year(2018)
- SABRE South (50 kg in Australia) scheduled to start in 2019
- DAMA/LIBRA phase 3 (1 ton) R&D underway

# Comparing DAMA with others

- not compatible with experiments with other targets

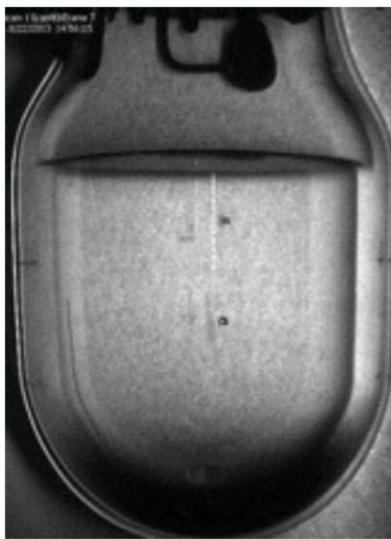

XENON collaboration, arXiv: 1507.07747, Science 349, 2015

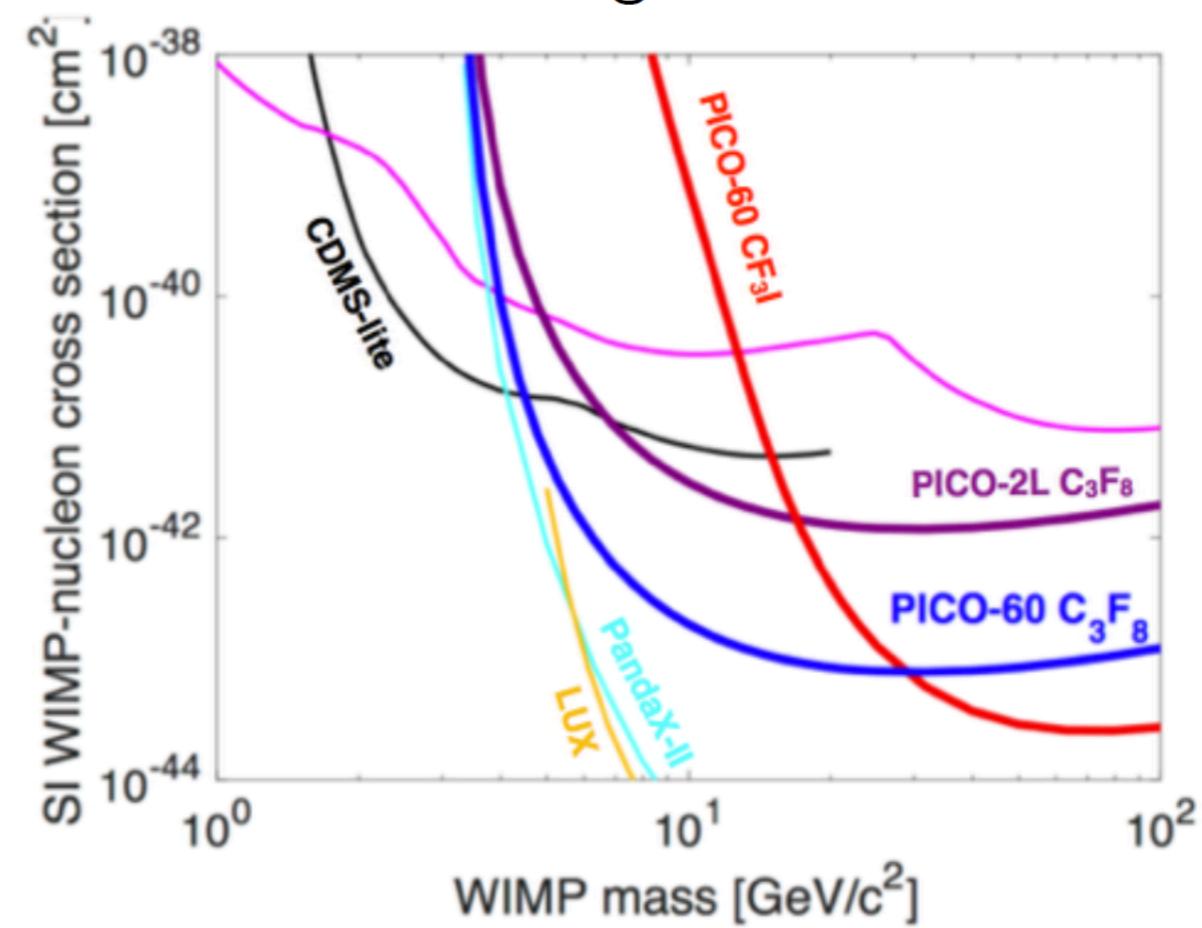

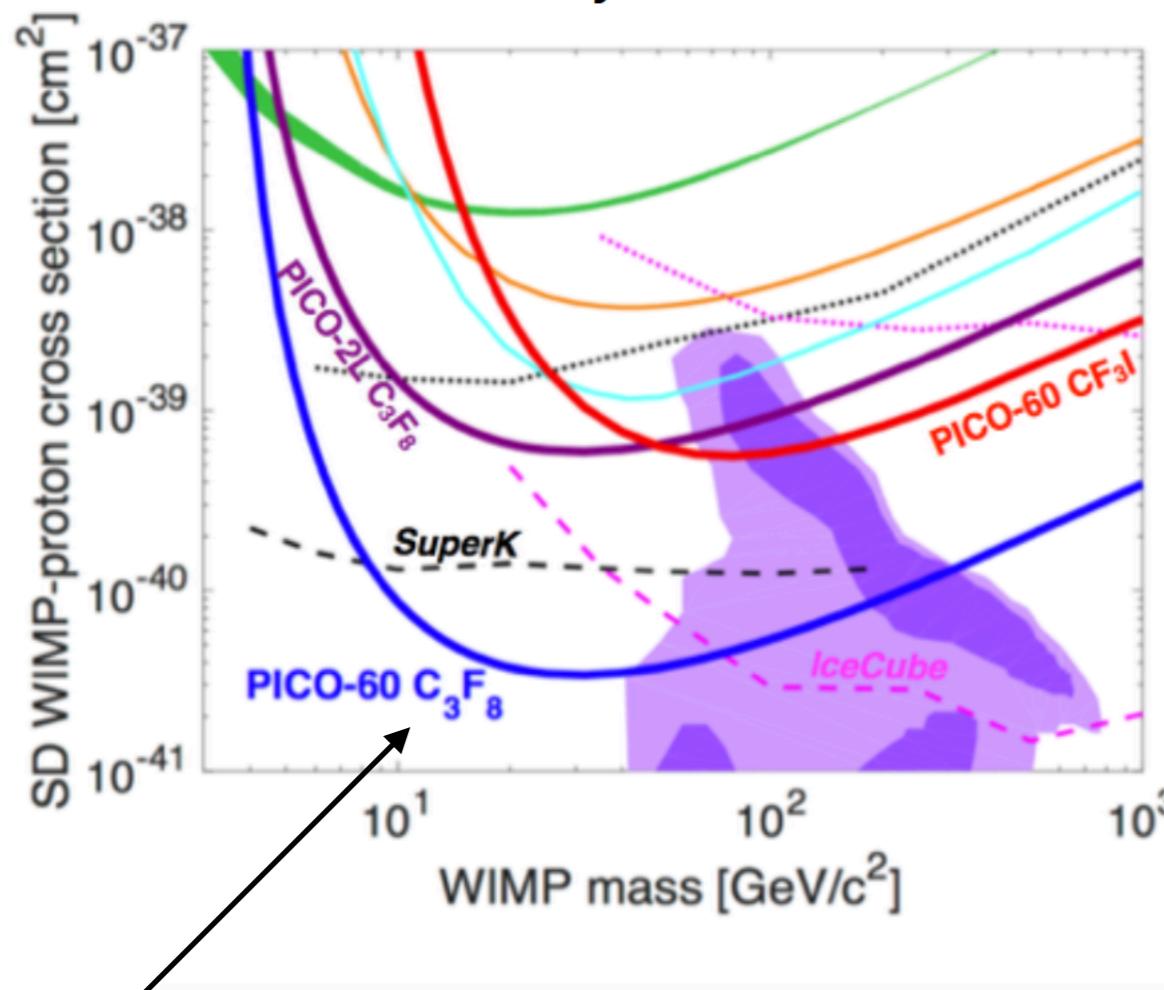

DAMA/LIBRA modulated spectrum as would be seen in XENON100 (for axial-vector WIMP-e⁻ scattering)

...but also with ER models,  
i.e. leptophilic

# Bubble chambers

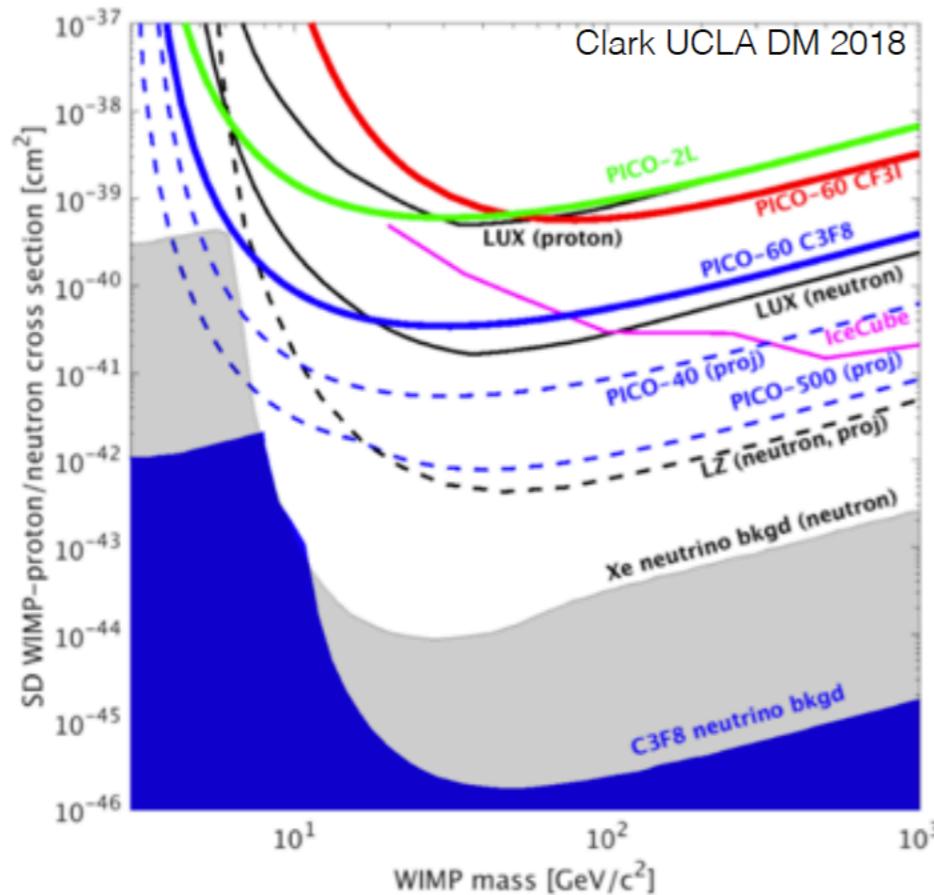

- Bubble nucleation in superheated liquids, target can include spin-dependent proton targets (F)
- Gammas and betas do not cause bubbles, alphas discriminated with acoustic signal
- PICO 60 6-2017 run 201 results with 52 kg active, 30 days at 3.3 keV threshold, then background limited

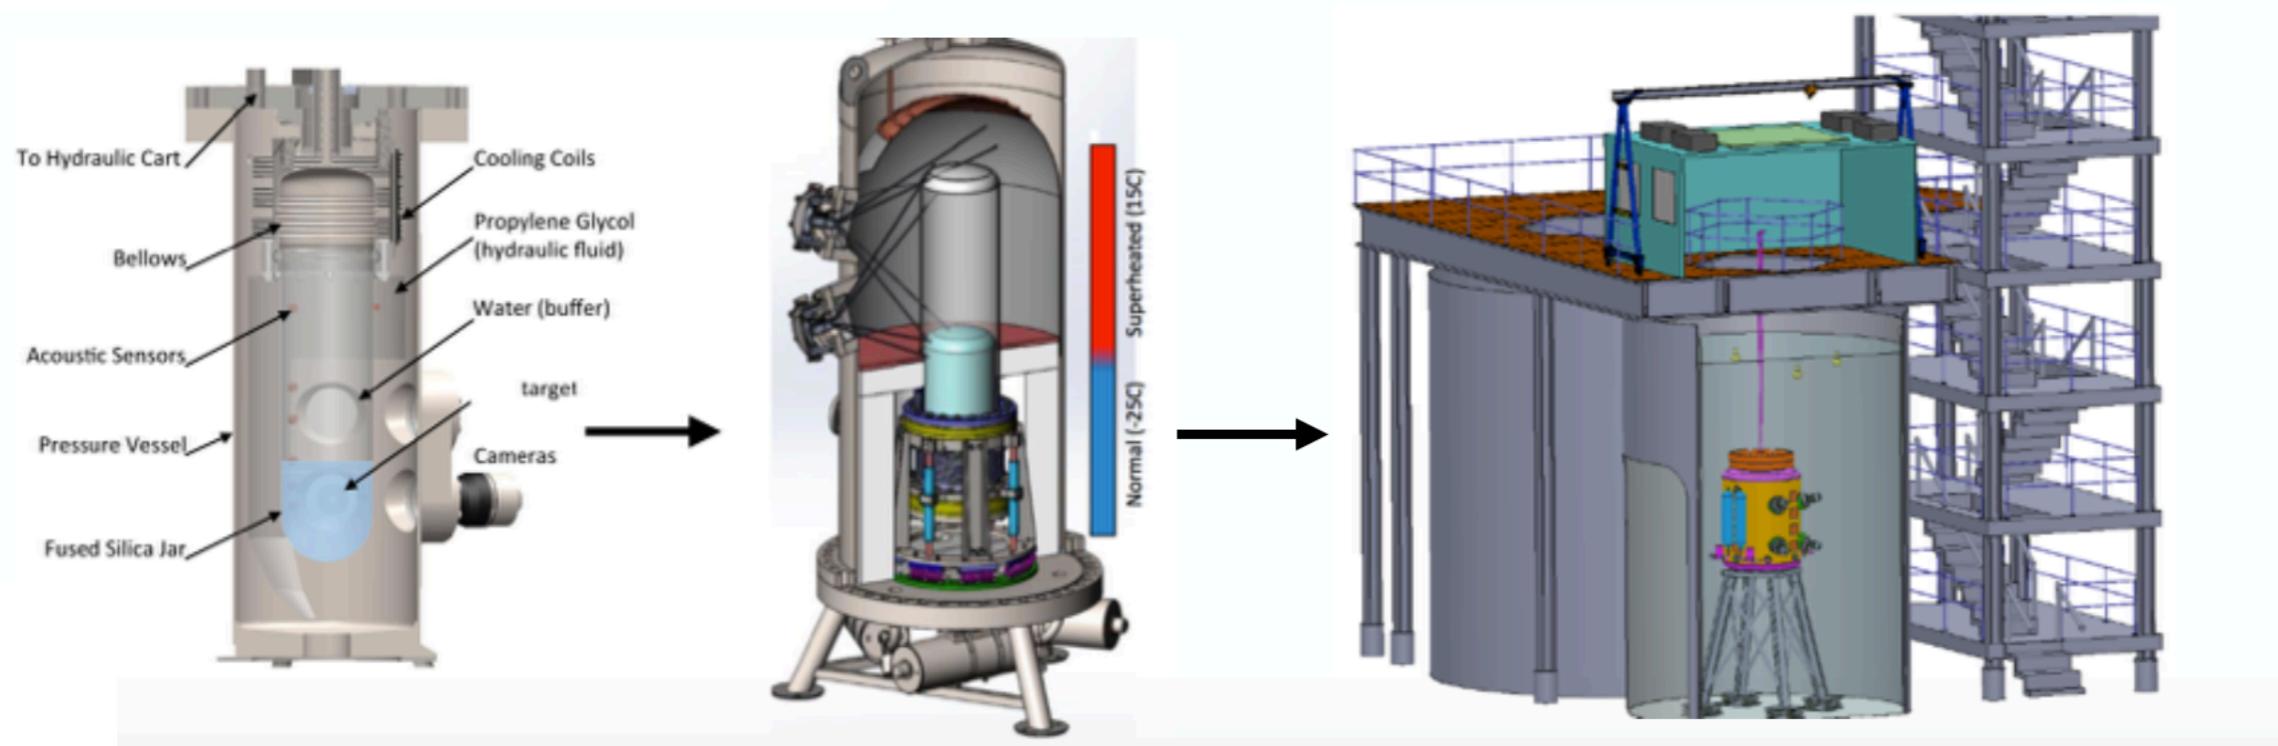

Phys. Rev. Lett. **118**, 251301 (2017)

- **best SD WIMP-proton limit:**  $3.4 \times 10^{-41} \text{ cm}^2$  at  $30 \text{ GeV}/c^2$

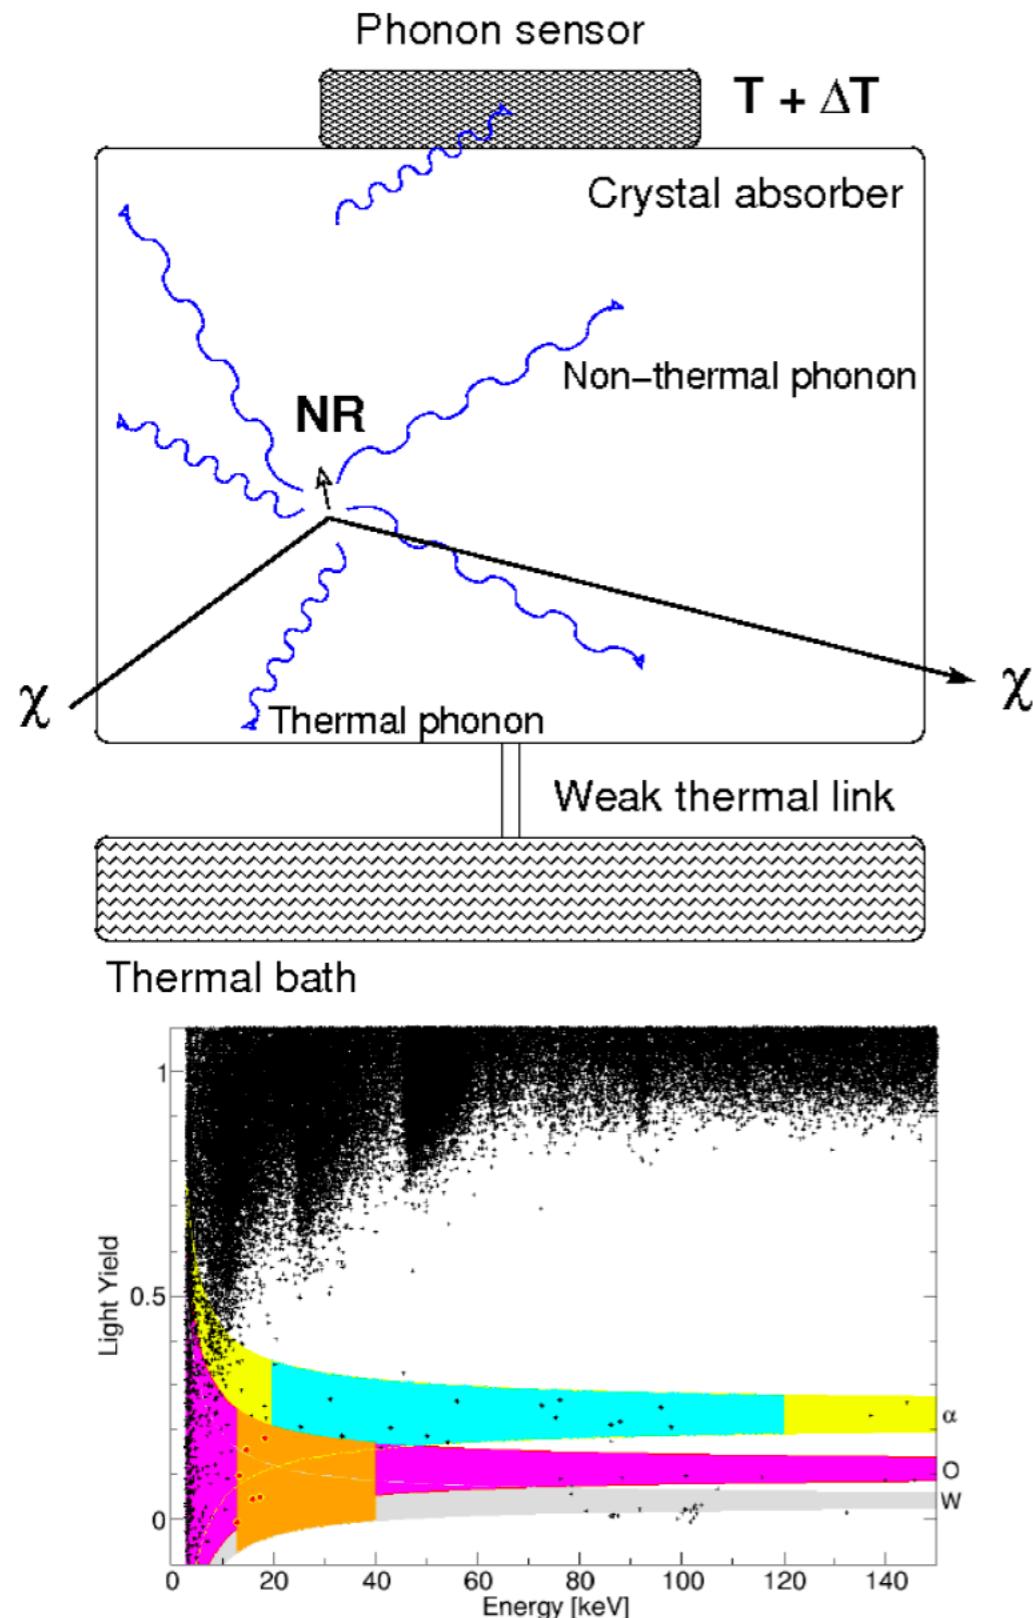

# PICO in the future ...

- Additional PICO 60 analyses forthcoming
- PICO 40L coming online this summer (2018) with  $\text{C}_3\text{F}_8$  target and inverted vessel
- PICO 500 scheduled to begin construction in 2019

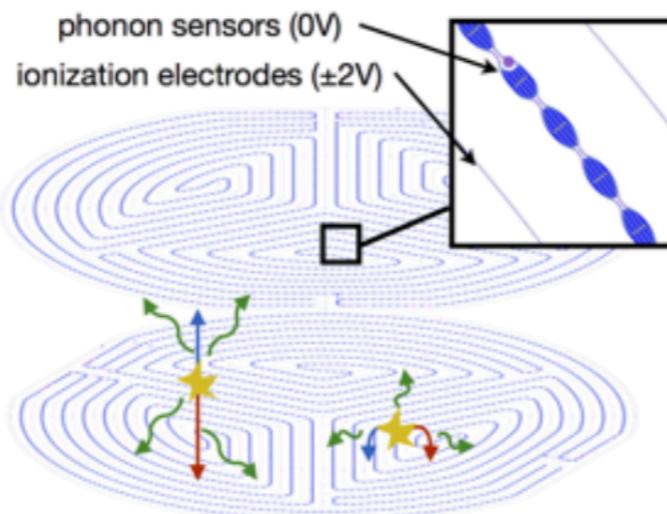

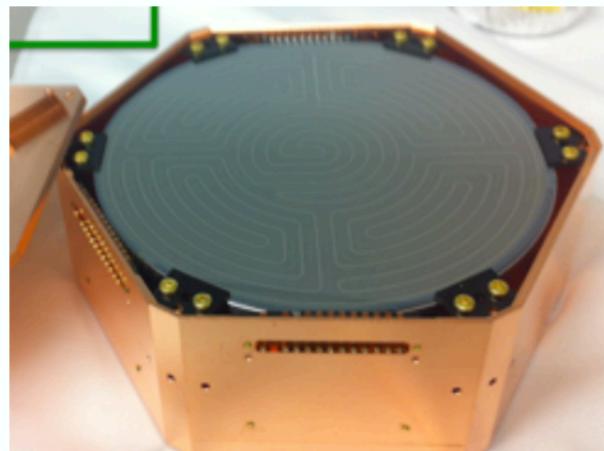

# Cryogenic bolometers

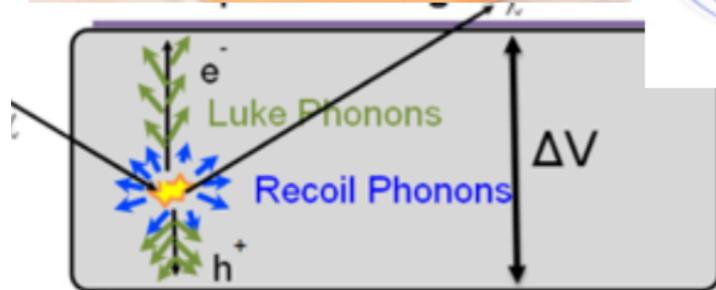

- Crystals at (10 – 100) mK
  - Temperature rise:  
$$\Delta T = E/C(T)$$
E.g. Ge at 20 mK,  $\Delta T = 20 \mu\text{K}$  for few keV recoil
  - Measurements of  $\Delta T$   
NTD: neutron transmutation-doped Ge sensors  
TES: Transition edge sensors
  - Discrimination: combination with **light** or **charge** read-out
  - Large separation of electronic and nuclear recoil bands
- Example from CRESST, EPJC 72 (2012) 1971

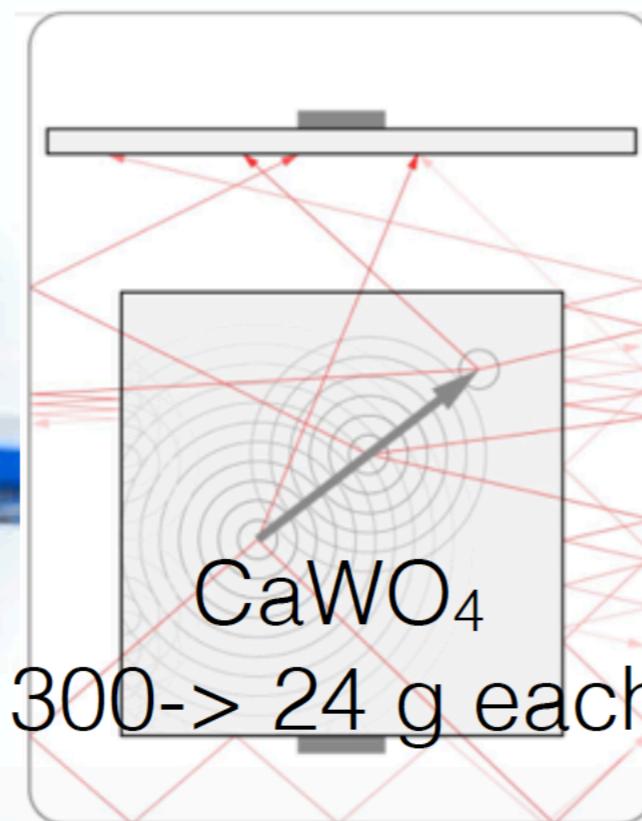

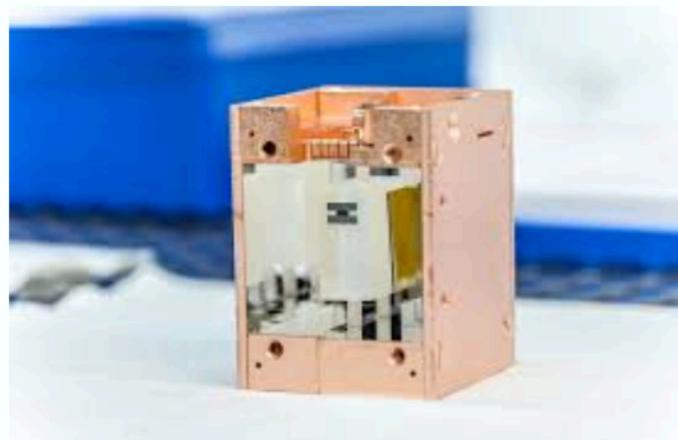

# Cryogenic bolometers

Ge, Si ~1 kg each

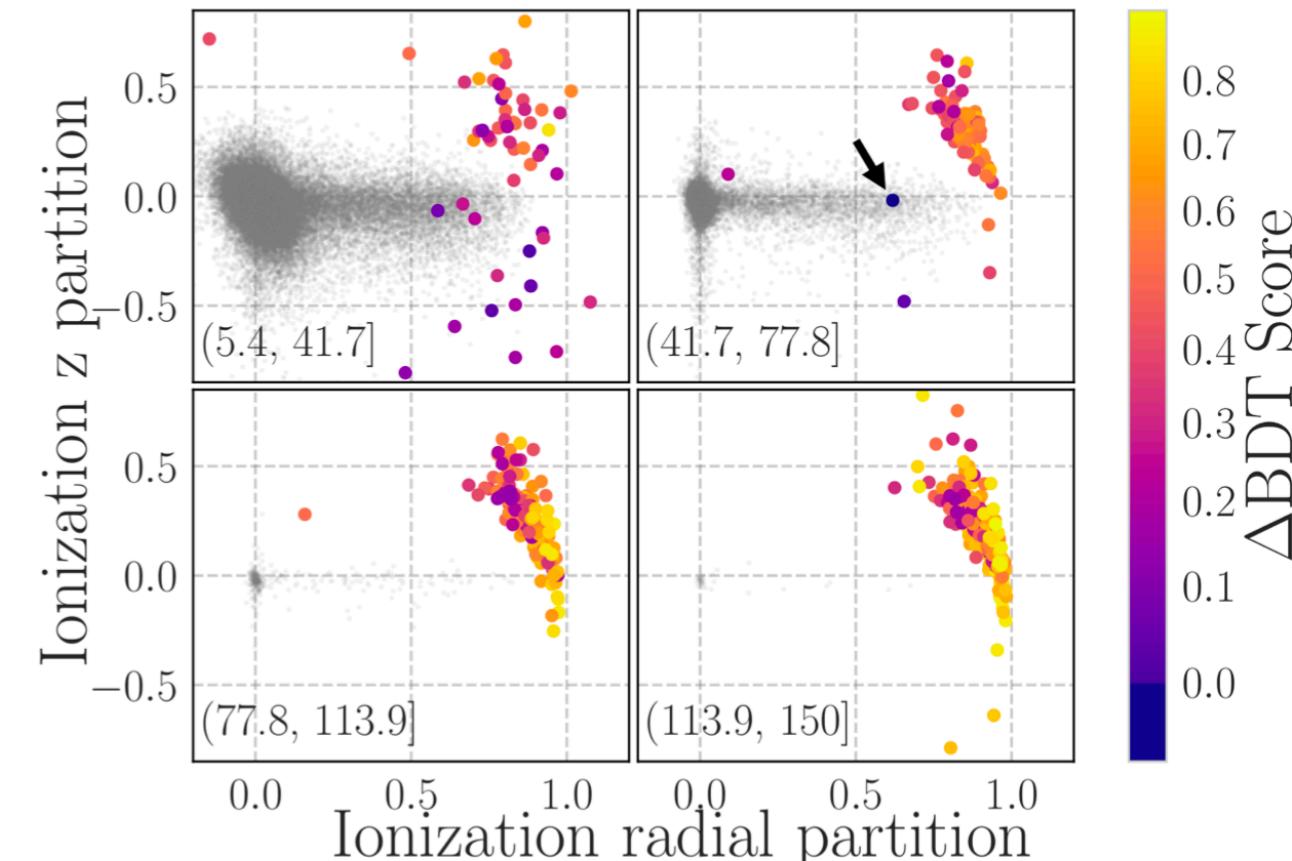

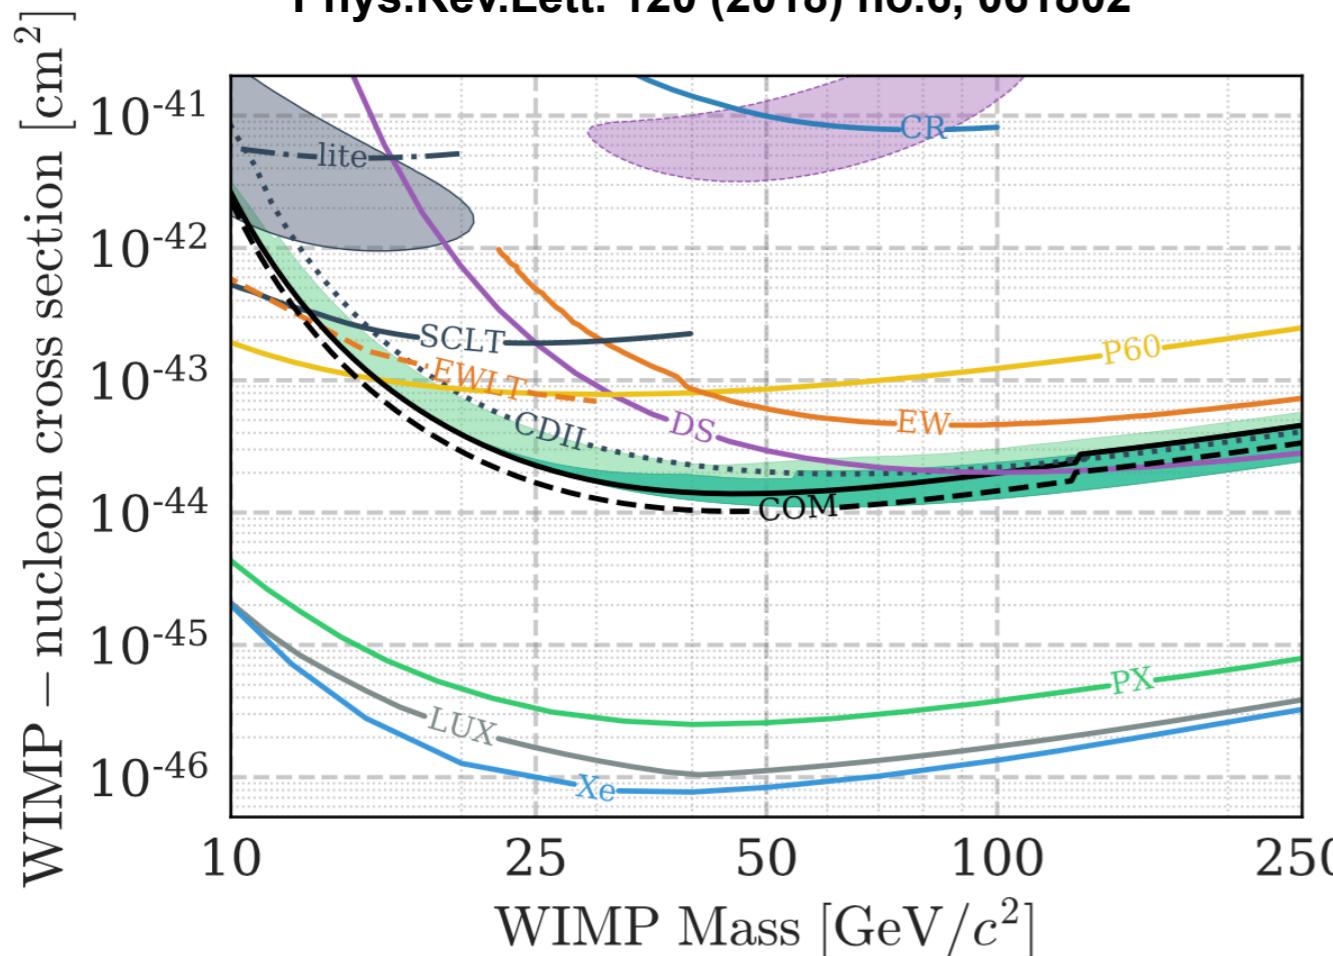

- SuperCDMS/EDELWEISS 2 techniques
  - HV (CDMSlite): Luke phonons: low threshold, but no discrimination
  - iZIP/FID: ionization and phonon signals with interleaved sensors discriminate against electronic recoils and surface events
- CRESST
  - CaWO<sub>4</sub> crystals for phonons and scintillation
- DAMIC
  - Si CCD

# SuperCDMS at Soudan

Phys.Rev.Lett. 120 (2018) no.6, 061802

- iZIP detectors
- 1690 kg days exposure
- single candidate observed, consistent with bkg
- **best limits for WIMP-germanium-nucleus interaction > 12  $\text{GeV}/c^2$**

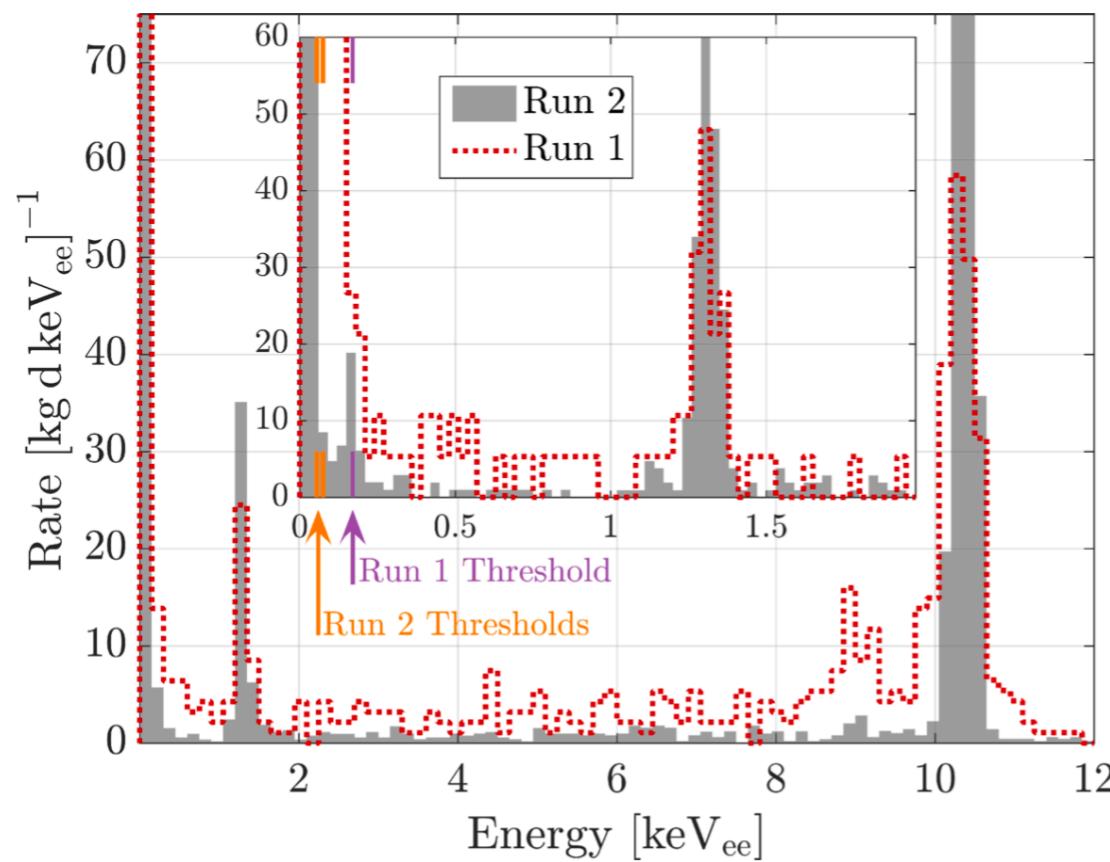

# Low-mass (1-10 GeV) dark matter: cryogenic bolometers

battle between low-threshold and low-background

CDMSlite, Phys. Rev. D 97, 022002 (2018)

## CDMSlite: HV operation

- no ER/NR discrimination: higher bkg
- but lowering the threshold: <100 eVee
- gain sensitivity for low-mass WIMPs

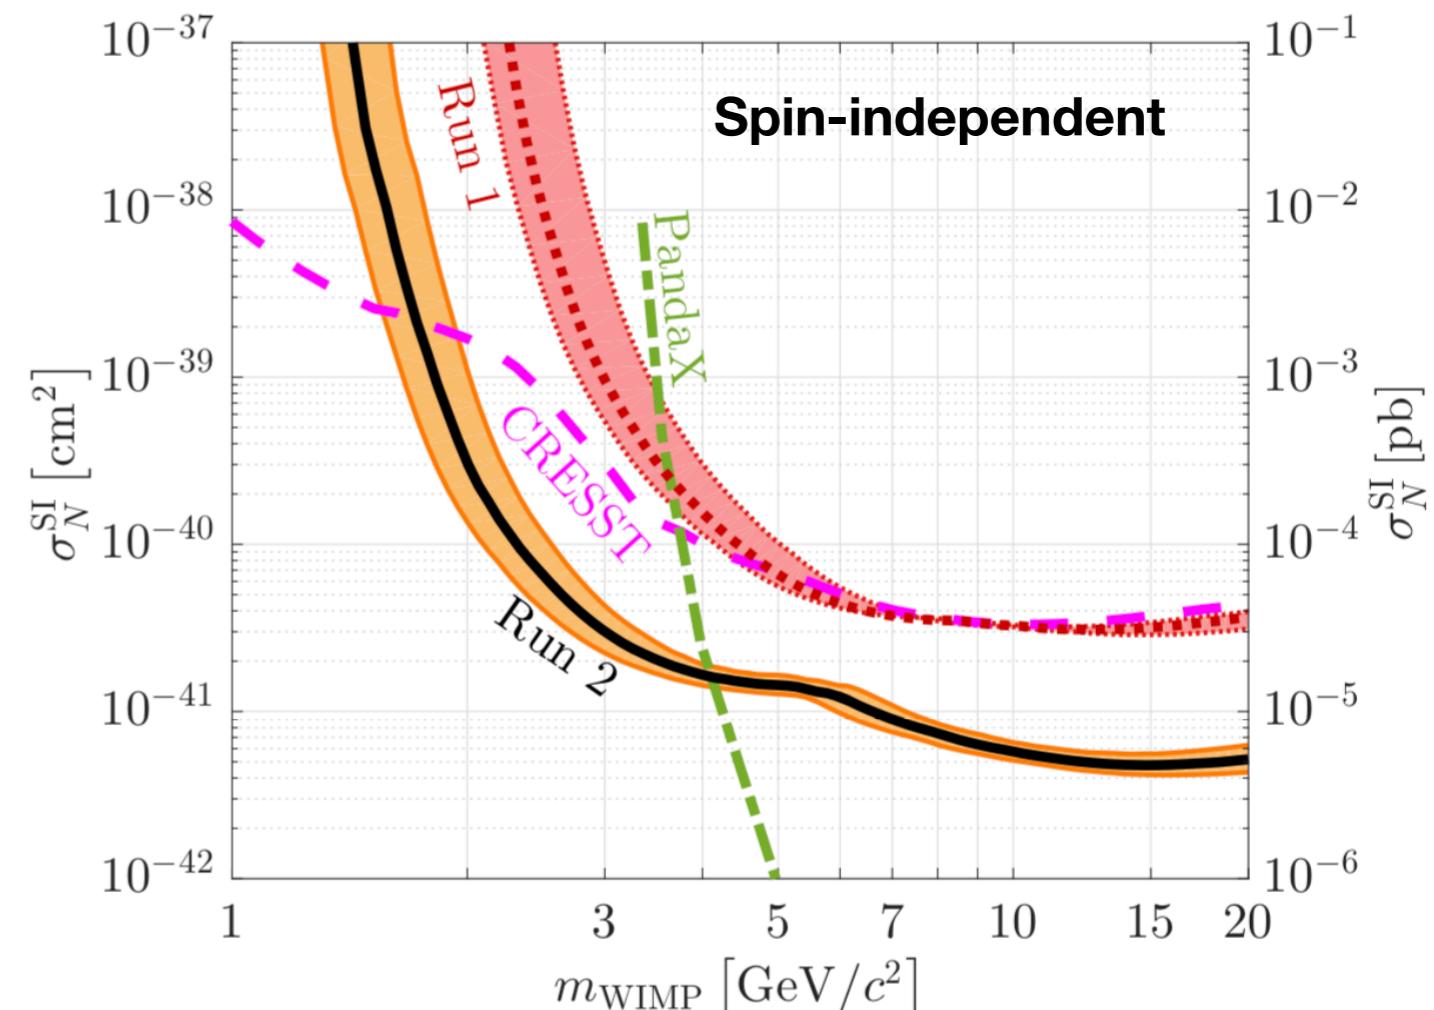

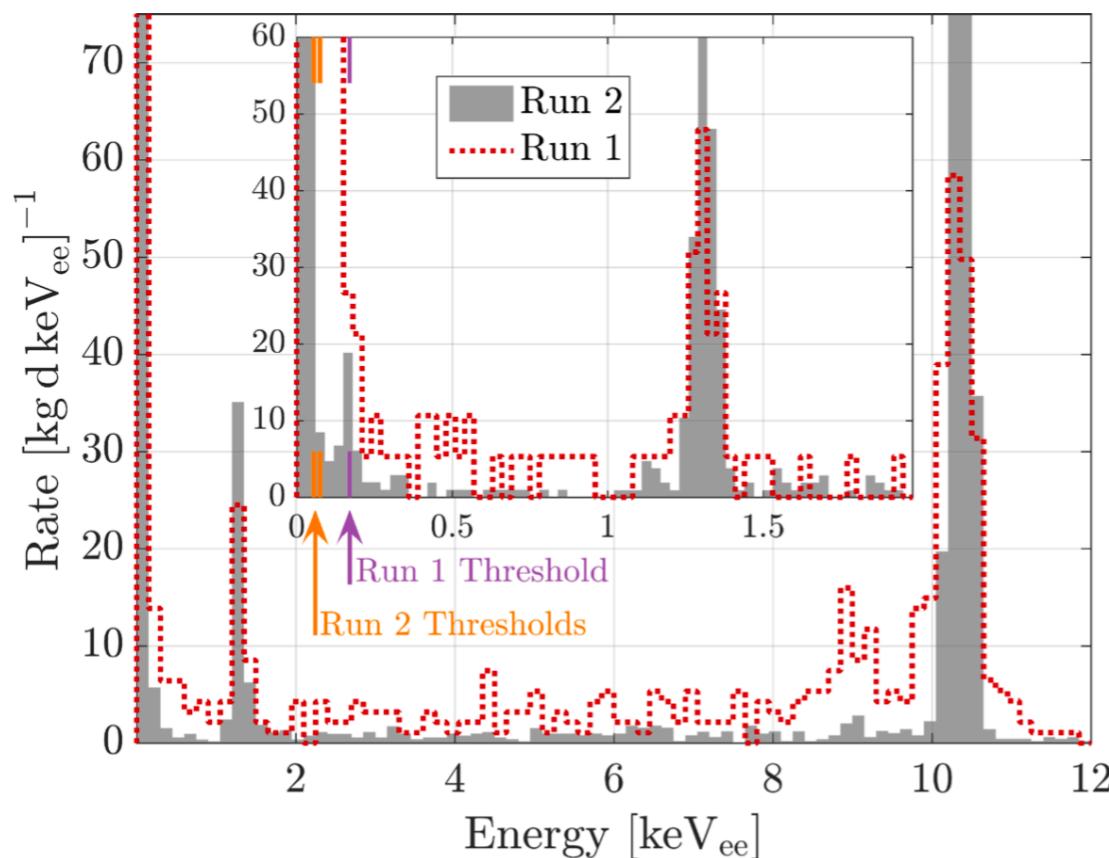

# Low-mass (1-10 GeV) dark matter: cryogenic bolometers

battle between low-threshold and low-background

CDMSlite, Phys. Rev. D 97, 022002 (2018)

## CDMSlite: HV operation

- no ER/NR discrimination: higher bkg
- but lowering the threshold: <100 eVee
- gain sensitivity for low-mass WIMPs

CRESST-III result from arXiv:1711.07692

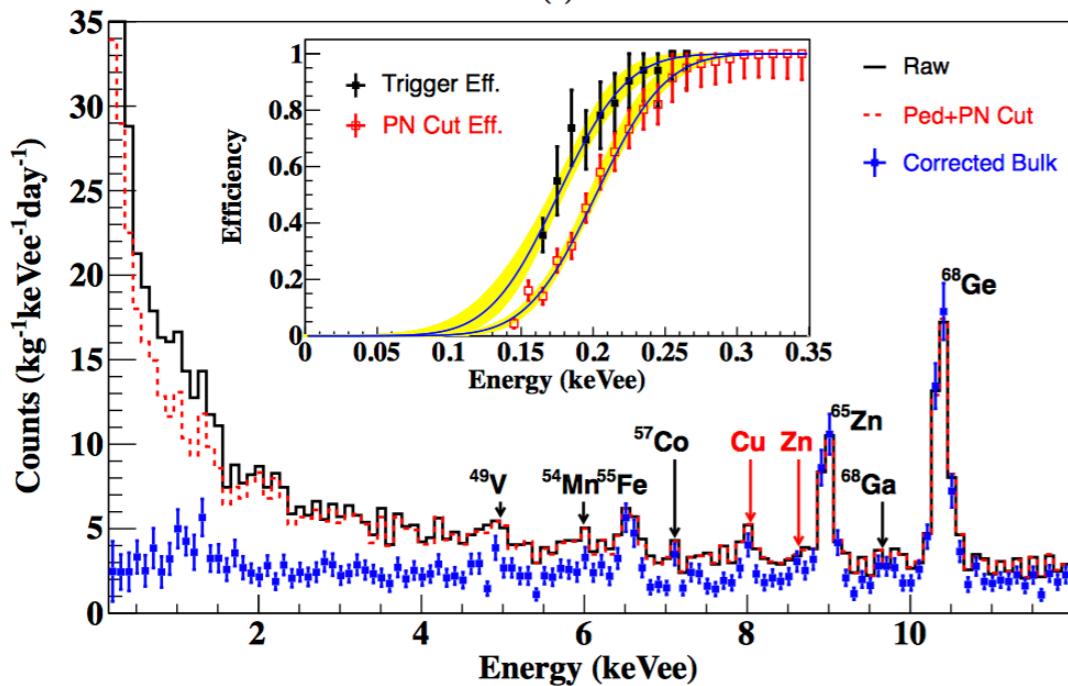

# Low-mass (1-10 GeV) dark matter: low-threshold counting

battle between low-threshold and low-background

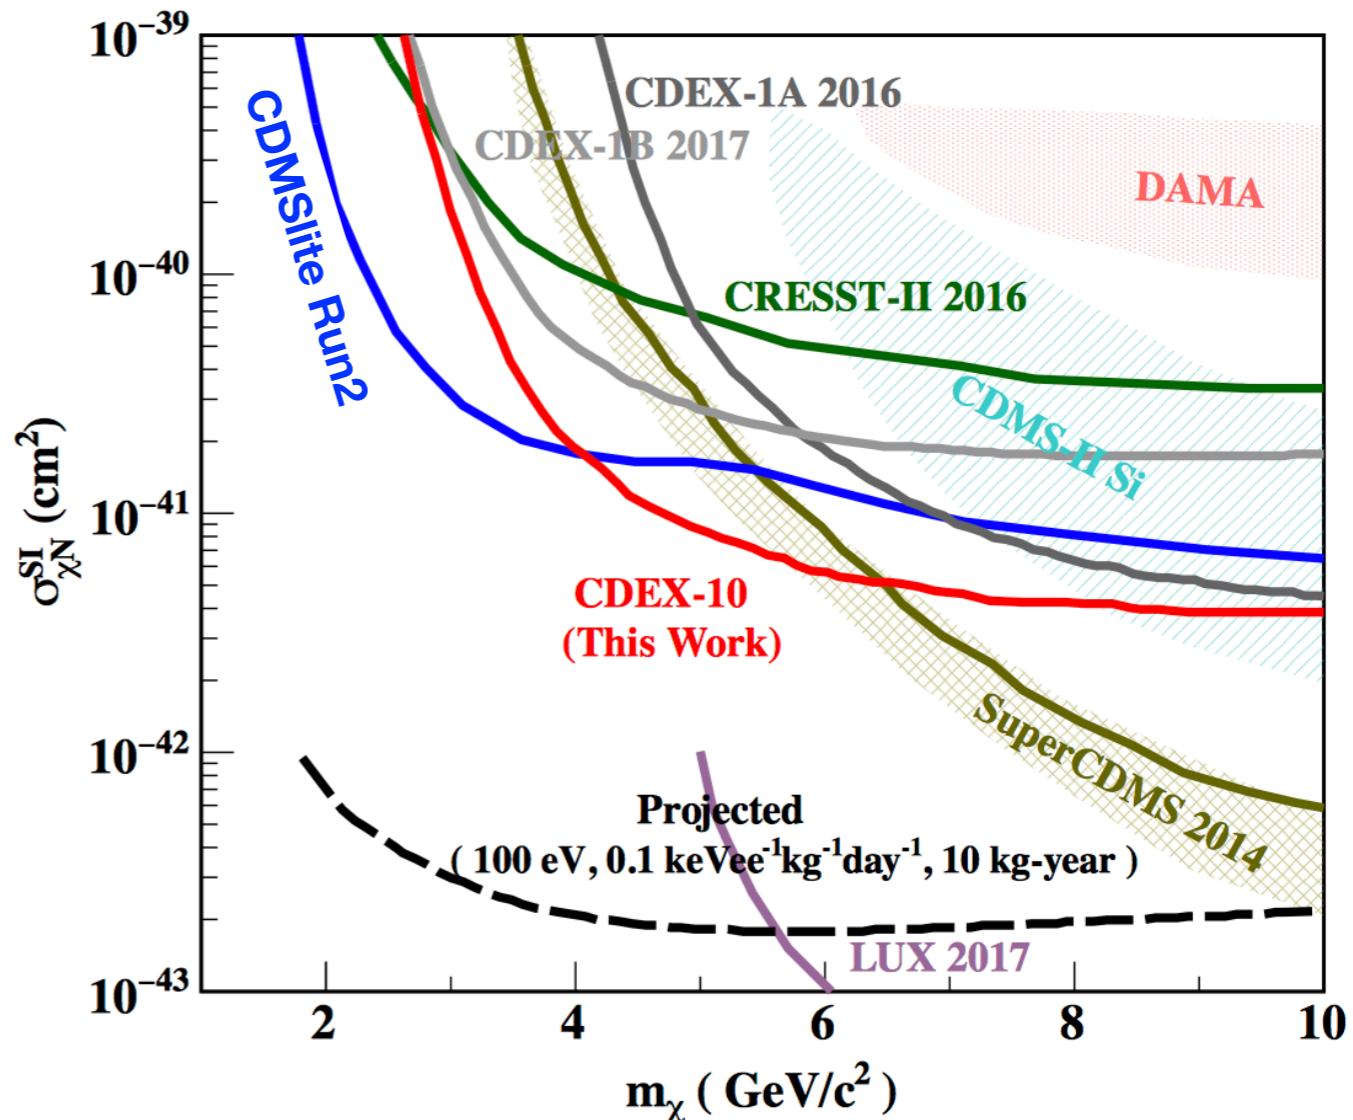

CoGeNT, CDEX: Ge Point Contact detector, low capacitance

## CDEX-10 at CJPL

- 10kg Ge detector in liquid nitrogen
- 102.8 kg-days exposure
- analysis threshold: 160 eVee
- residual bkg rate:  $\sim 2.5$  evt/keVee/kg/day
- improved SI & SD-n limits at 5  $\text{GeV}/c^2$

## CDEX, arXiv:1802.09016

# Liquid Noble Detectors

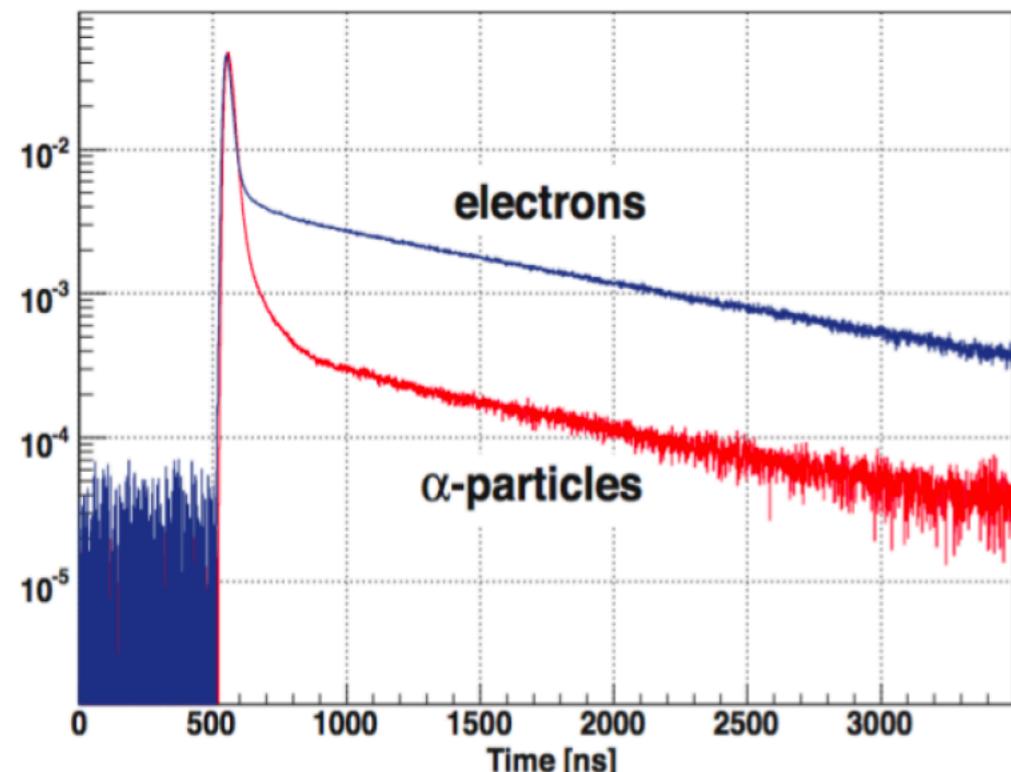

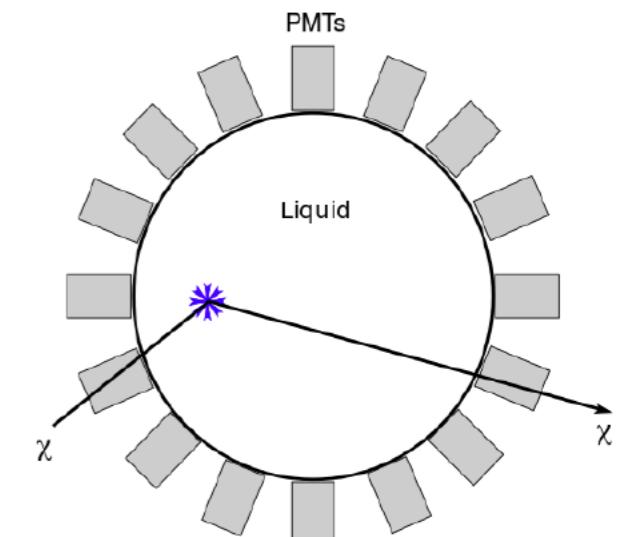

- Large masses and homogeneous targets (LNe, LAr & LXe)  
Two detector concepts: single & double phase
- 3D position reconstruction → fiducialization
- Transparent to their own scintillation light

	LNe	LAr	LXe
Z (A)	10 (20)	18 (40)	54 (131)
Density [g/cm <sup>3</sup> ]	1.2	1.4	3.0
Scintillation $\lambda$	78 nm	125 nm	178 nm
BP [K] at 1 atm	27	87	165
Ionization [e <sup>-</sup> /keV]*	46	42	64
Scintillation [ $\gamma$ /keV]*	7	40	46

\* for electronic recoils

# Liquid Noble Detectors: Single Phase

- High light yield using  $4\pi$  photosensor coverage
- Position resolution in the cm range
- Pulse shape discrimination (PSD) from scintillation

Scintillation decay constants of argon measured by ArDM

- Very different singlet and triplet lifetimes in argon & neon
- Relative amplitudes depend on particle type → discrimination

DEAP-I obtained  $10^{-8}$  discrimination in LAr above 25 keV<sub>ee</sub> (50% acceptance)

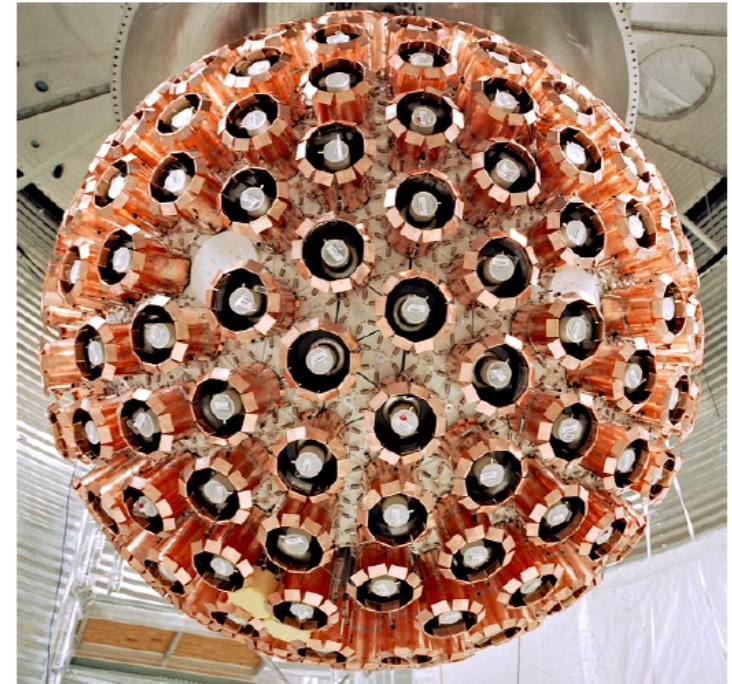

M. G. Boulay *et al.*, arXiv:0904.2930

→ PSD less powerful in LXe: similar decay constants XMASS, NIM. A659 (2011) 161

# Liquid Noble Detectors: Single Phase

**DEAP** - LAr detector at SNOLAB, Canada  
Dark matter Experiment with Argon and Pulse shape discrimination

- 3 600 kg total mass & 1 ton FV
- 2-inch thick ultraclean acrylic vessel
- Wavelength-shifter inside the vessel
- Light guides to the PMTs

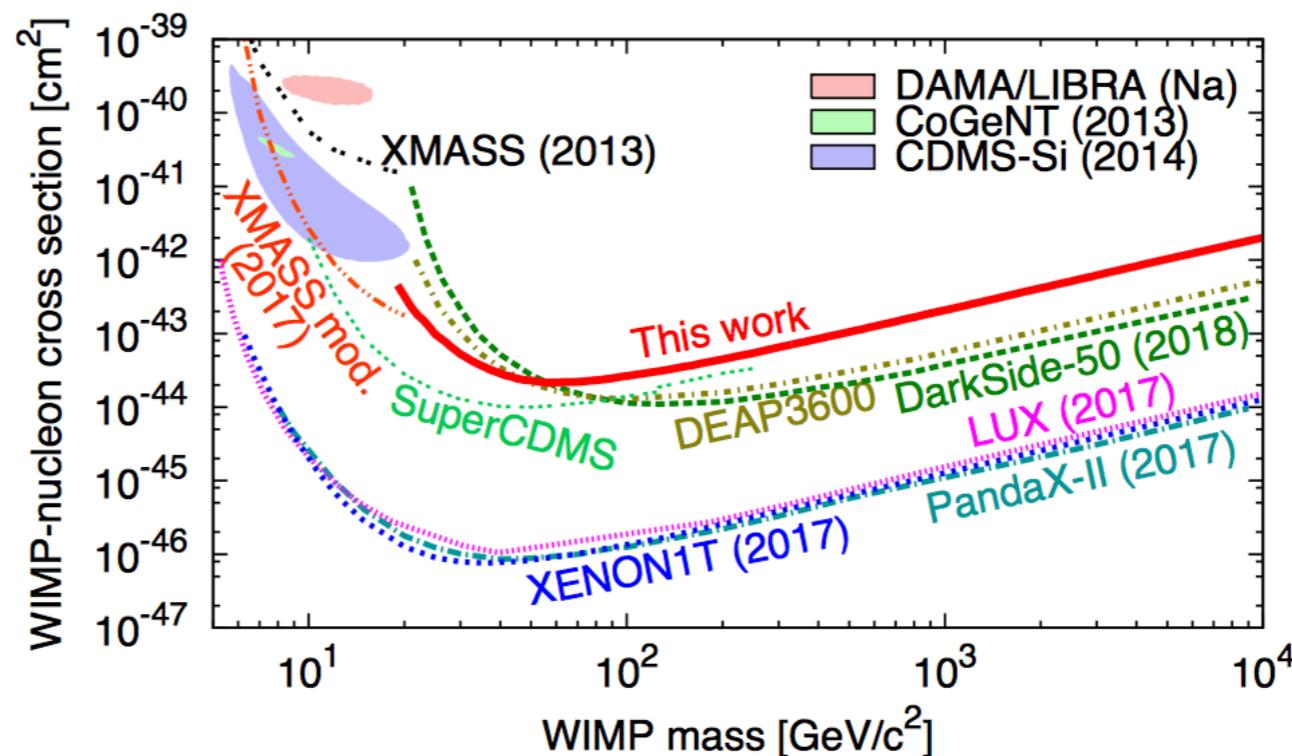

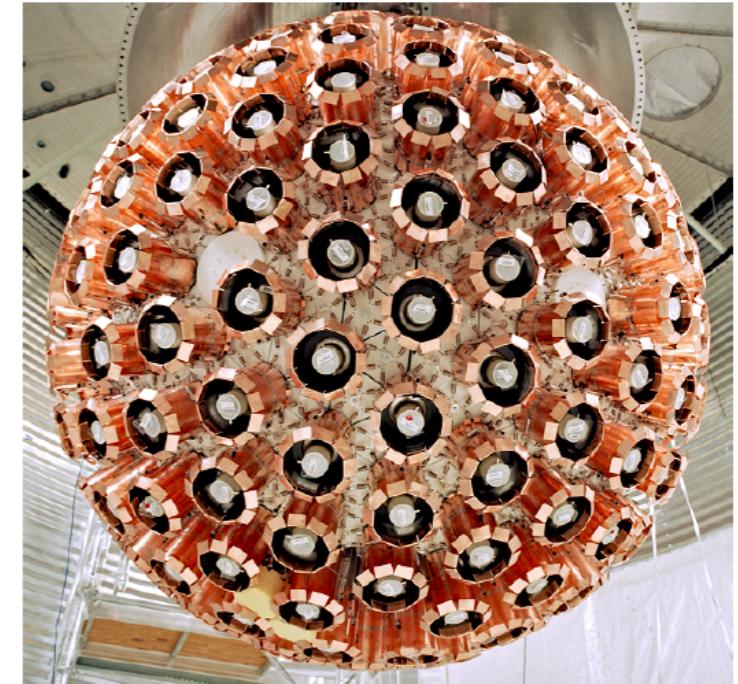

**XMASS** - LXe detector at Kamioka, Japan

- 1 ton total LXe mass & 800 kg FV
- Ultra-clean PMTs directly in contact with the LXe target
- High light yield measured: 14.7 PE/keVee  
 $E_{th} = 0.3 \text{ keV}_{ee}$

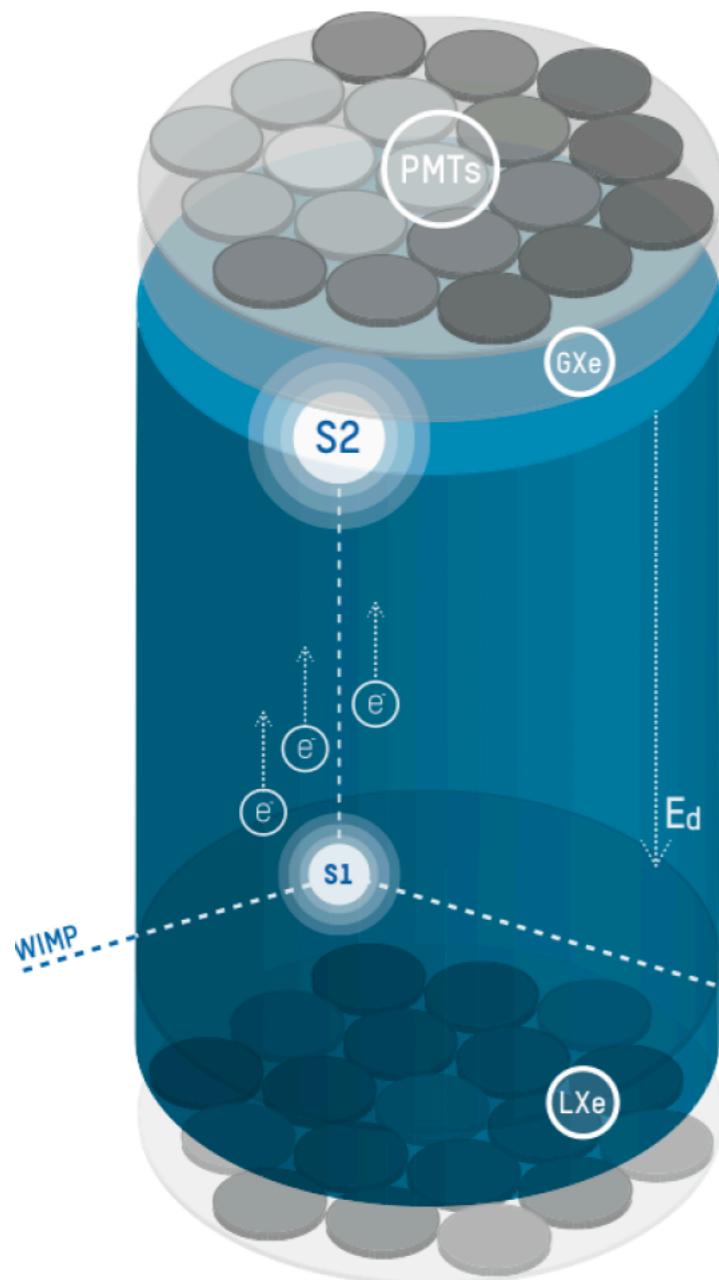

# Liquid Noble Detectors: Single Phase

**DEAP** - LAr detector at SNOLAB, Canada  
Dark matter Experiment with Argon and Pulse shape discrimination

- 3 600 kg total mass & 1 ton FV
- 2-inch thick ultraclean acrylic vessel
- Wavelength-shifter inside the vessel
- Light guides to the PMTs

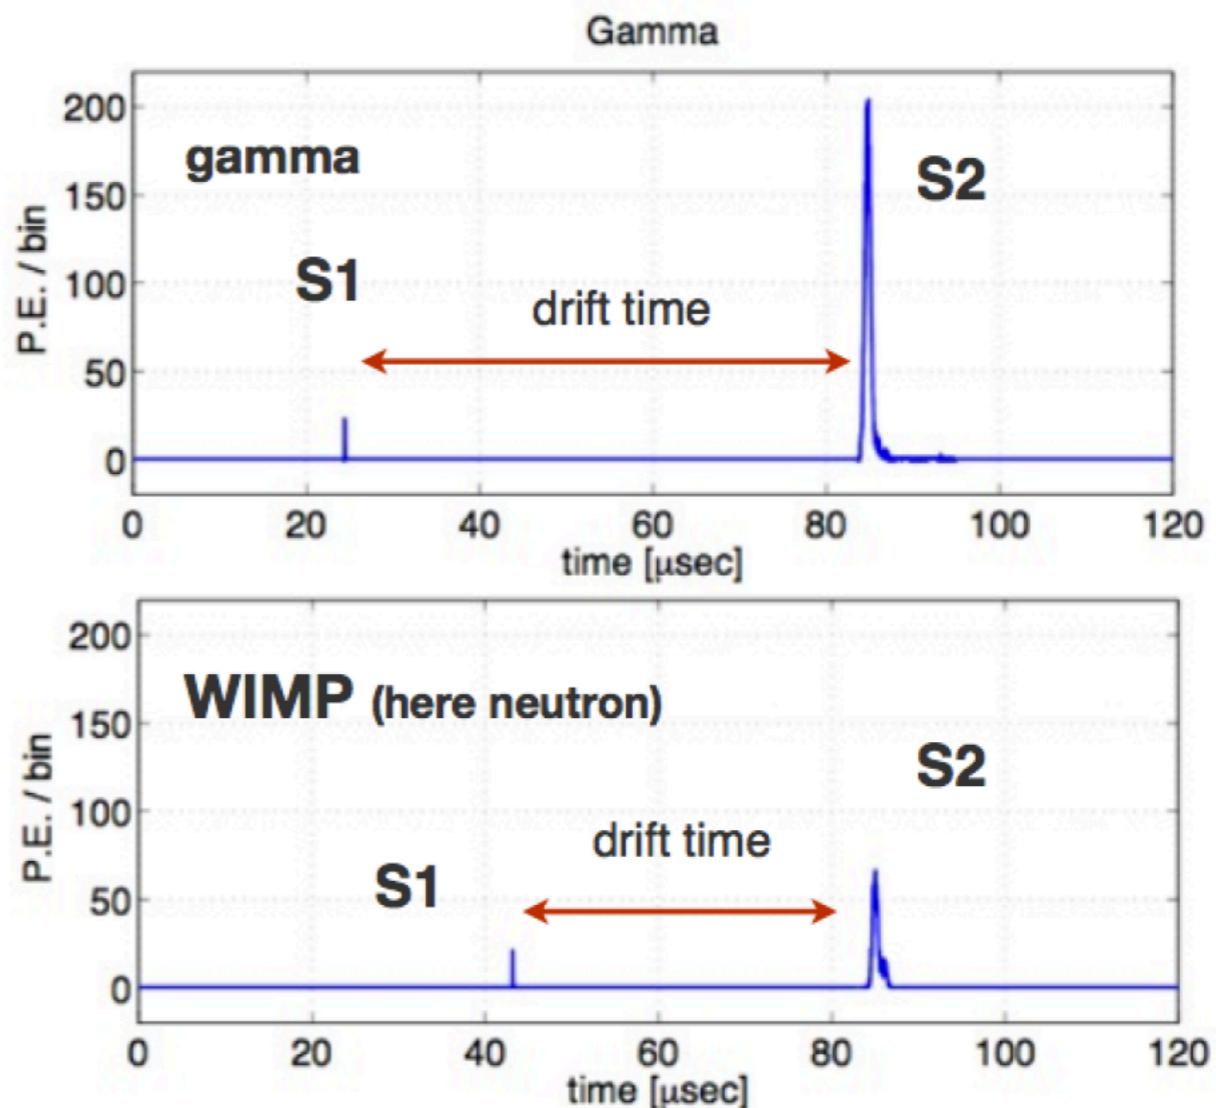

# Liquid Noble Detectors: Double Phase TPC

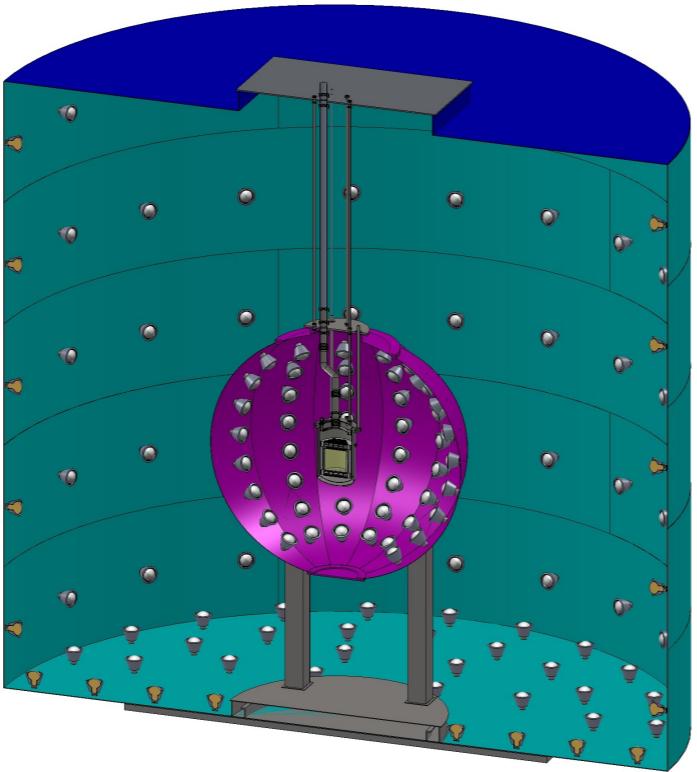

- Drift field
- Electronegative purity
- Position resolution

- Scintillation signal (S1)
  - Charges drift to the liquid-gas surface
  - Proportional signal (S2)
- Electron- /nuclear recoil discrimination

# DarkSide-50 and -20t

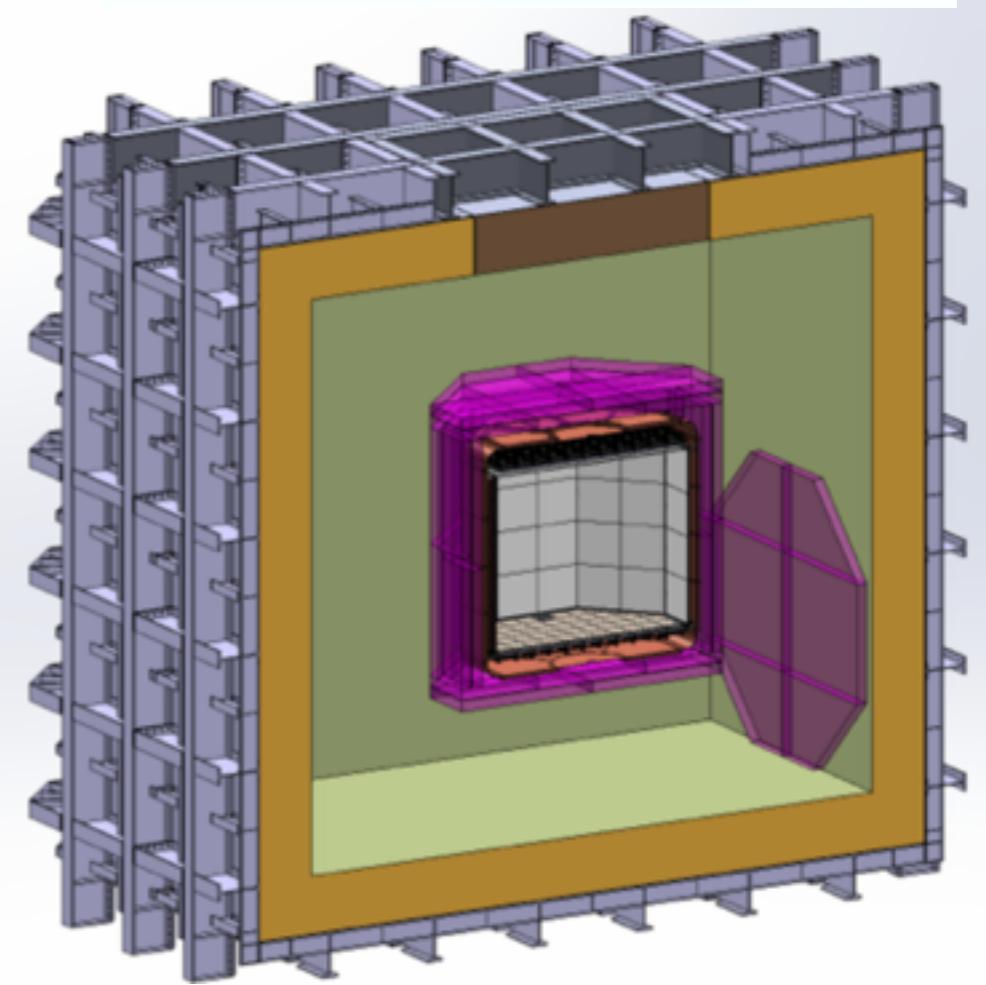

## DarkSide-50

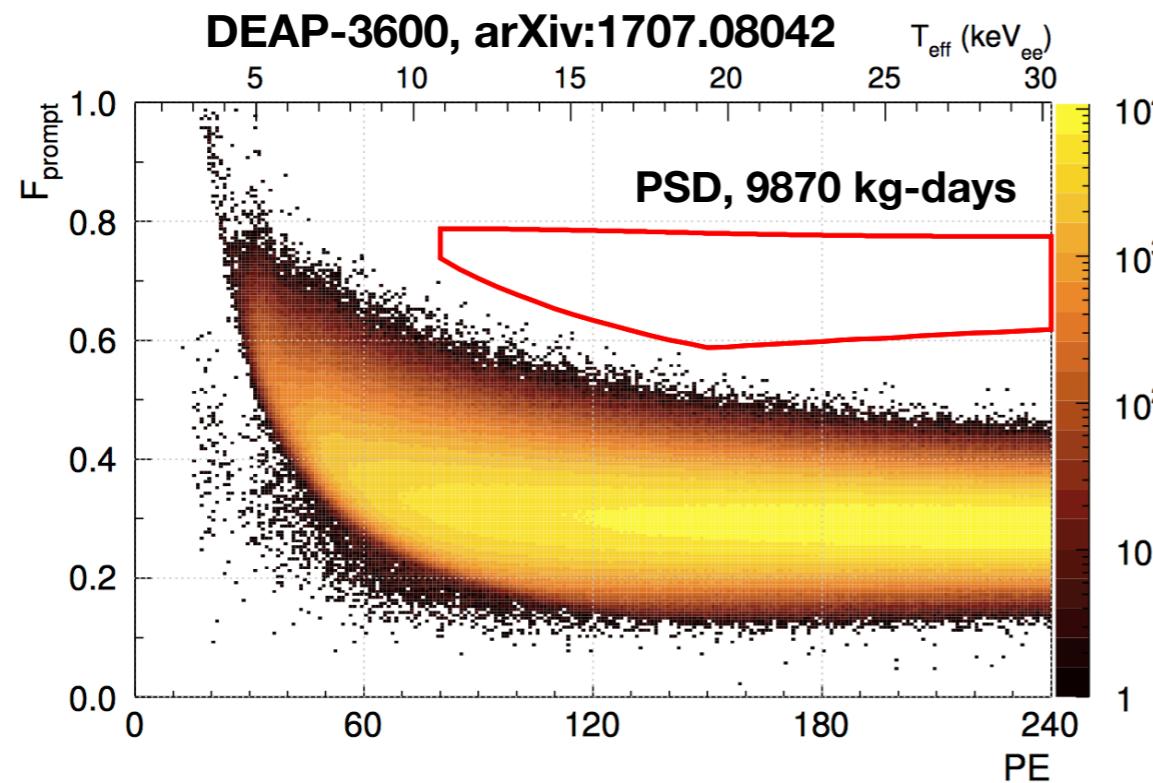

- Detector inside Borexino counting facility at LNGS (Italy)
- 50 kg depleted argon from underground sources  
 $> 1000$  reduction in  $^{39}\text{Ar}$  level
- Pulse shape & charge/light ratio for particle discrimination  
Pulse-shape separation  $> 10^7$
- Hamamatsu R11065 as photosensor  
Challenge: operation of PMTs at LAr temperatures  
→ plan to use SiPMs in the next generation detector

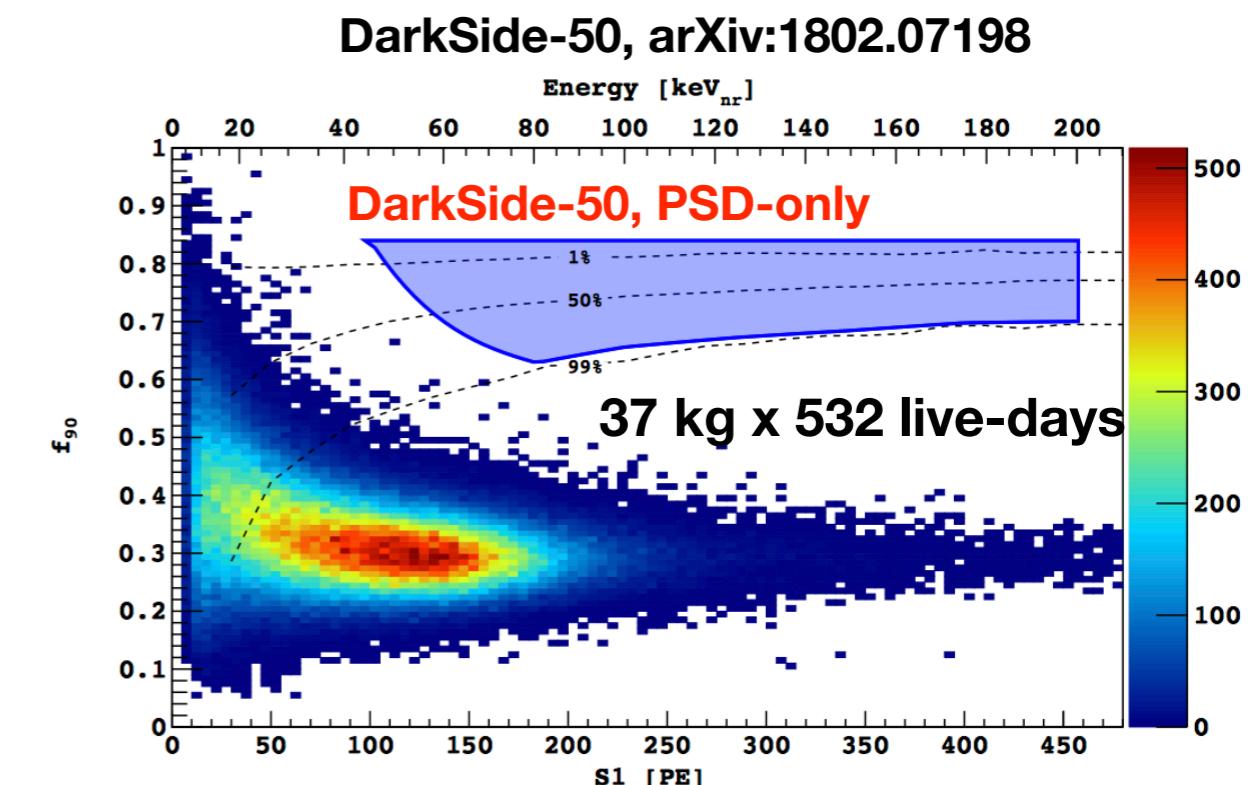

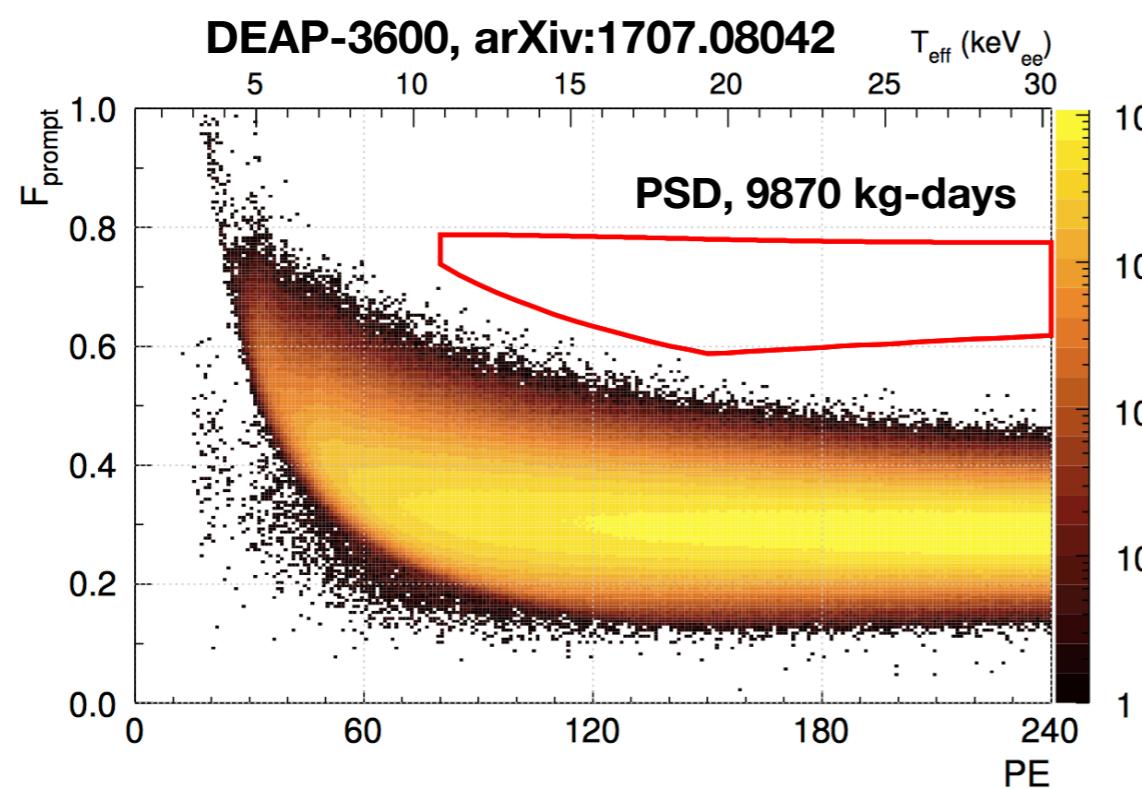

- **DarkSide-20t**
  - Scheduled for 2021
  - Utilizing underground argon
  - Atmospheric LAr veto, DUNE style cryostat possible
  - Background free
- Global Argon Dark Matter Collaboration
  - 300 t in 2027

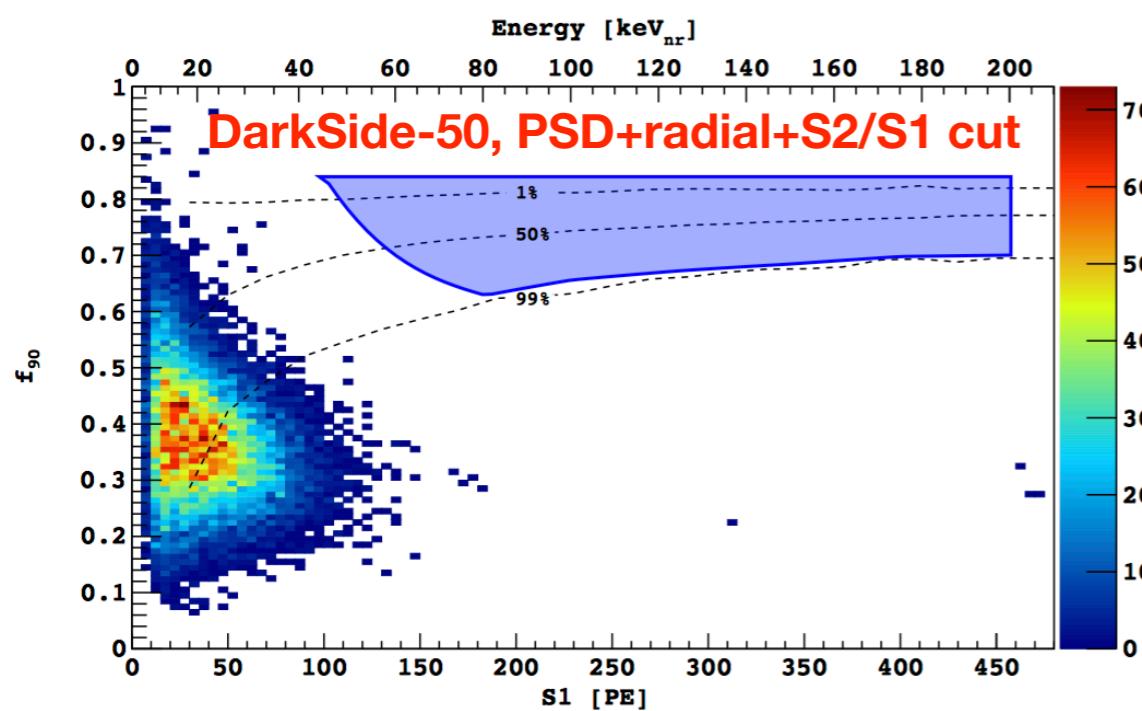

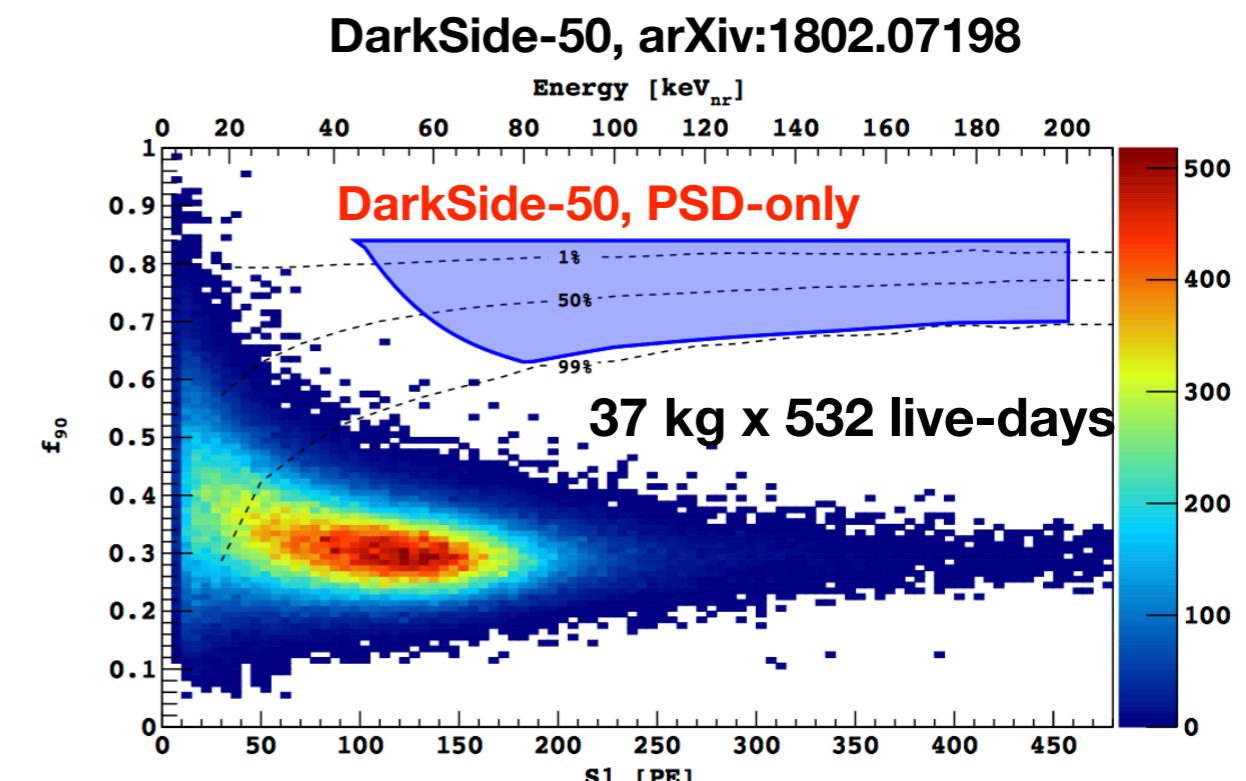

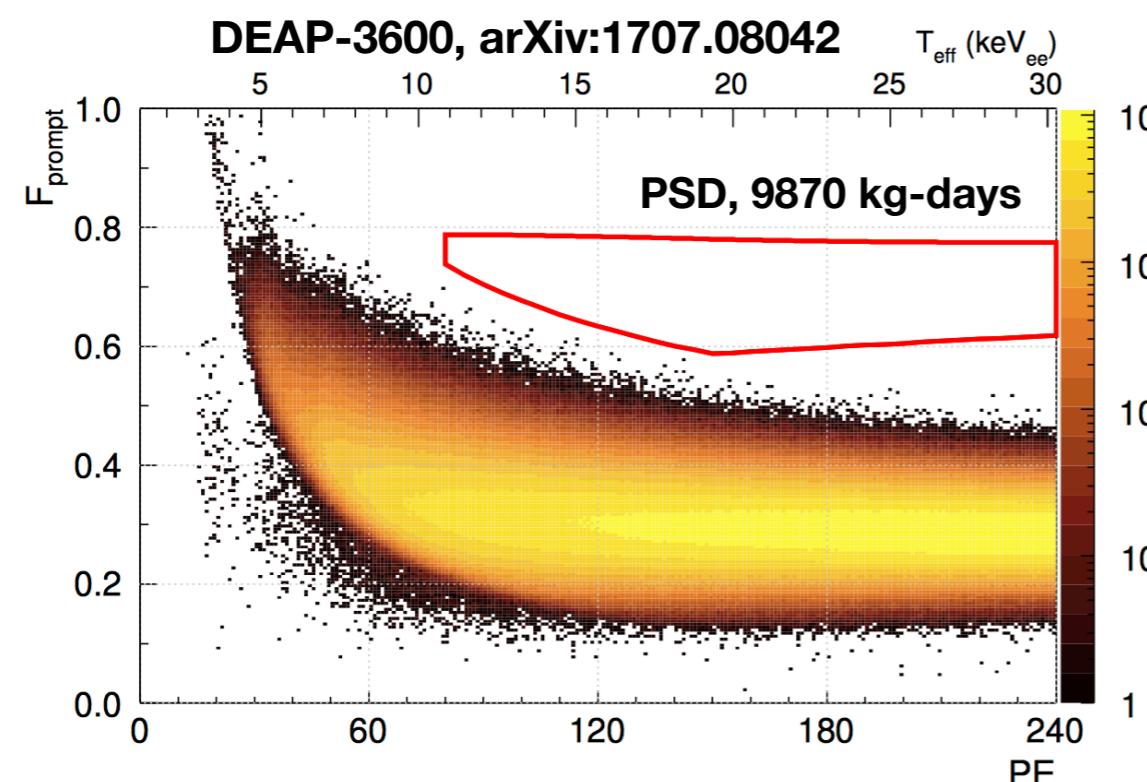

# Liquid Argon results: DarkSide-50 & DEAP-3600

Model-independent Effective field theory (EFT), e.g. XENON100, Phys.Rev. D96 (2017) no.4, 042004

# Low-mass (1-10 GeV) dark matter: liquid argon

big improvement with S2-only search in DarkSide-50

DarkSide-50, arXiv:1802.06994

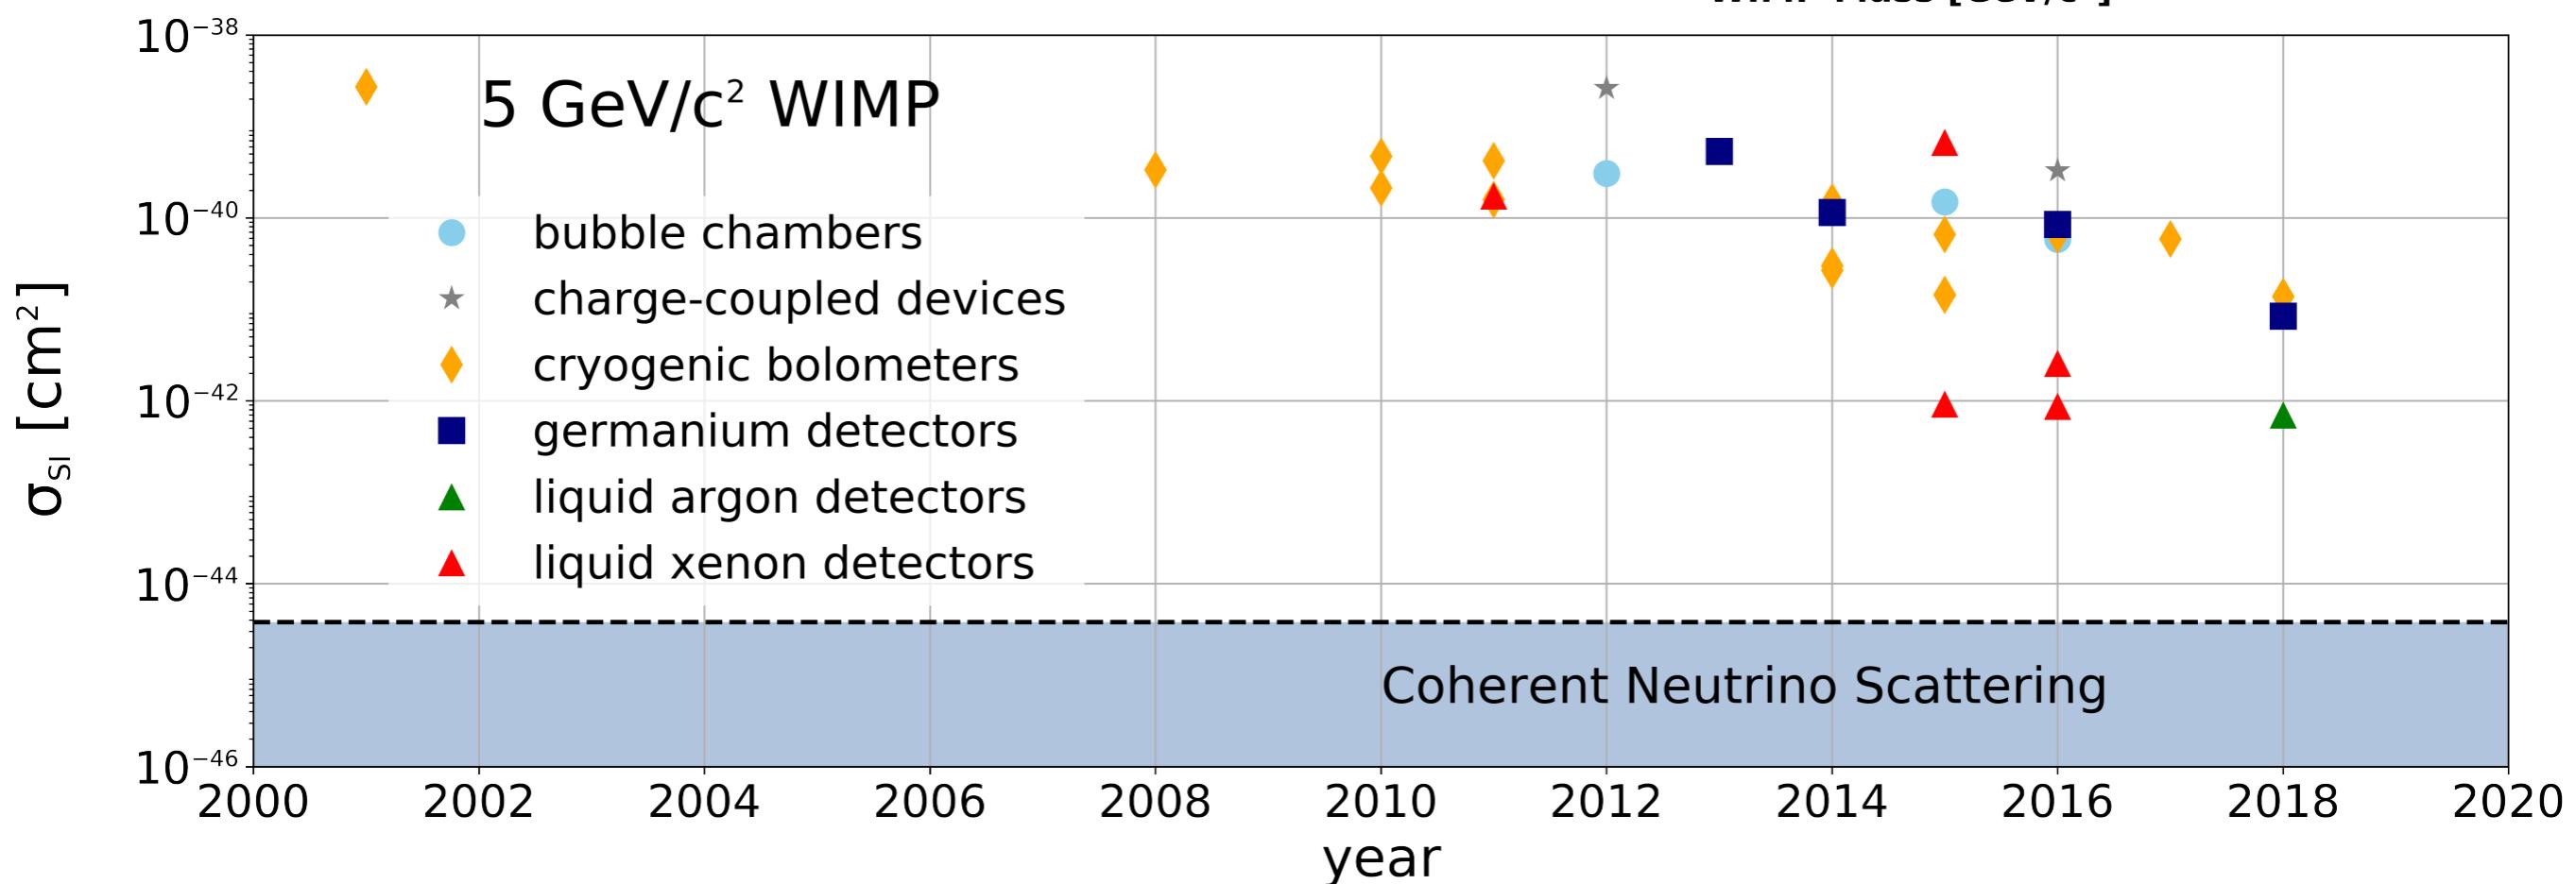

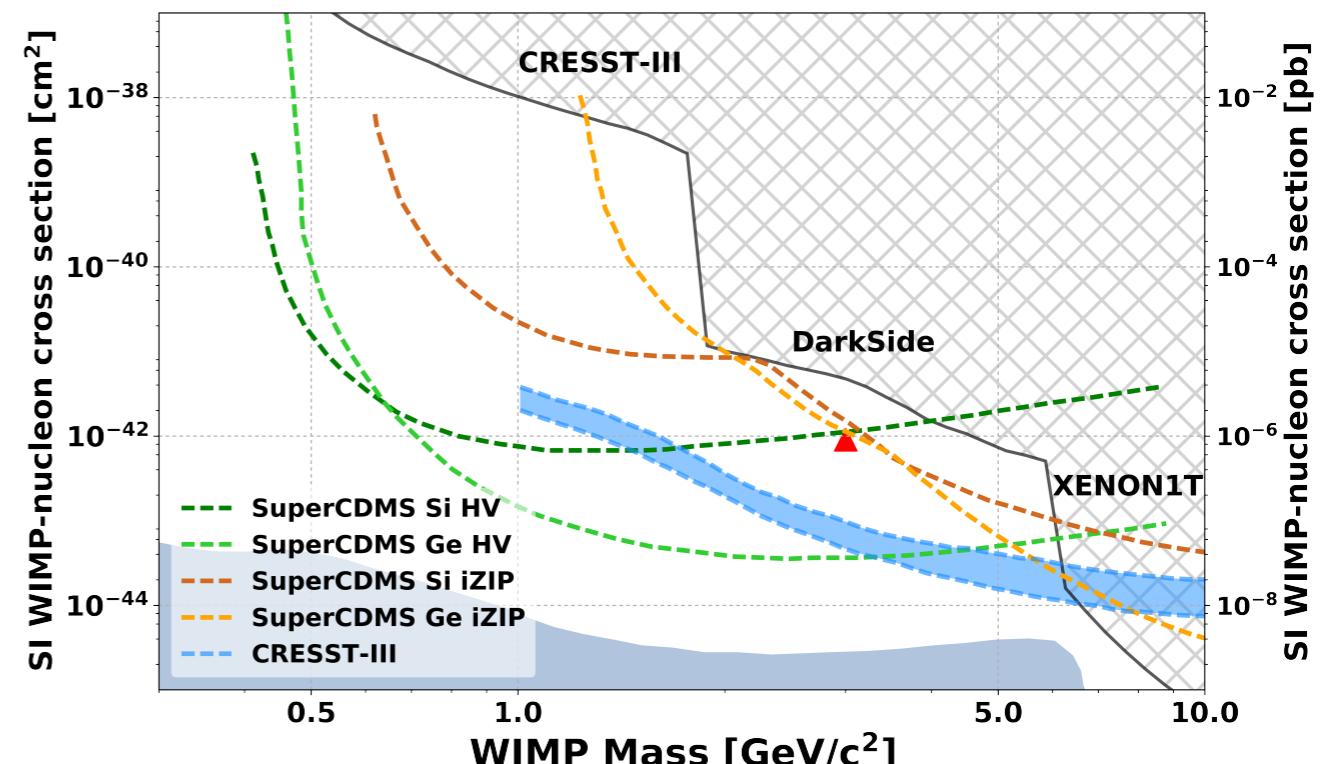

## DarkSide-50 S2-only search

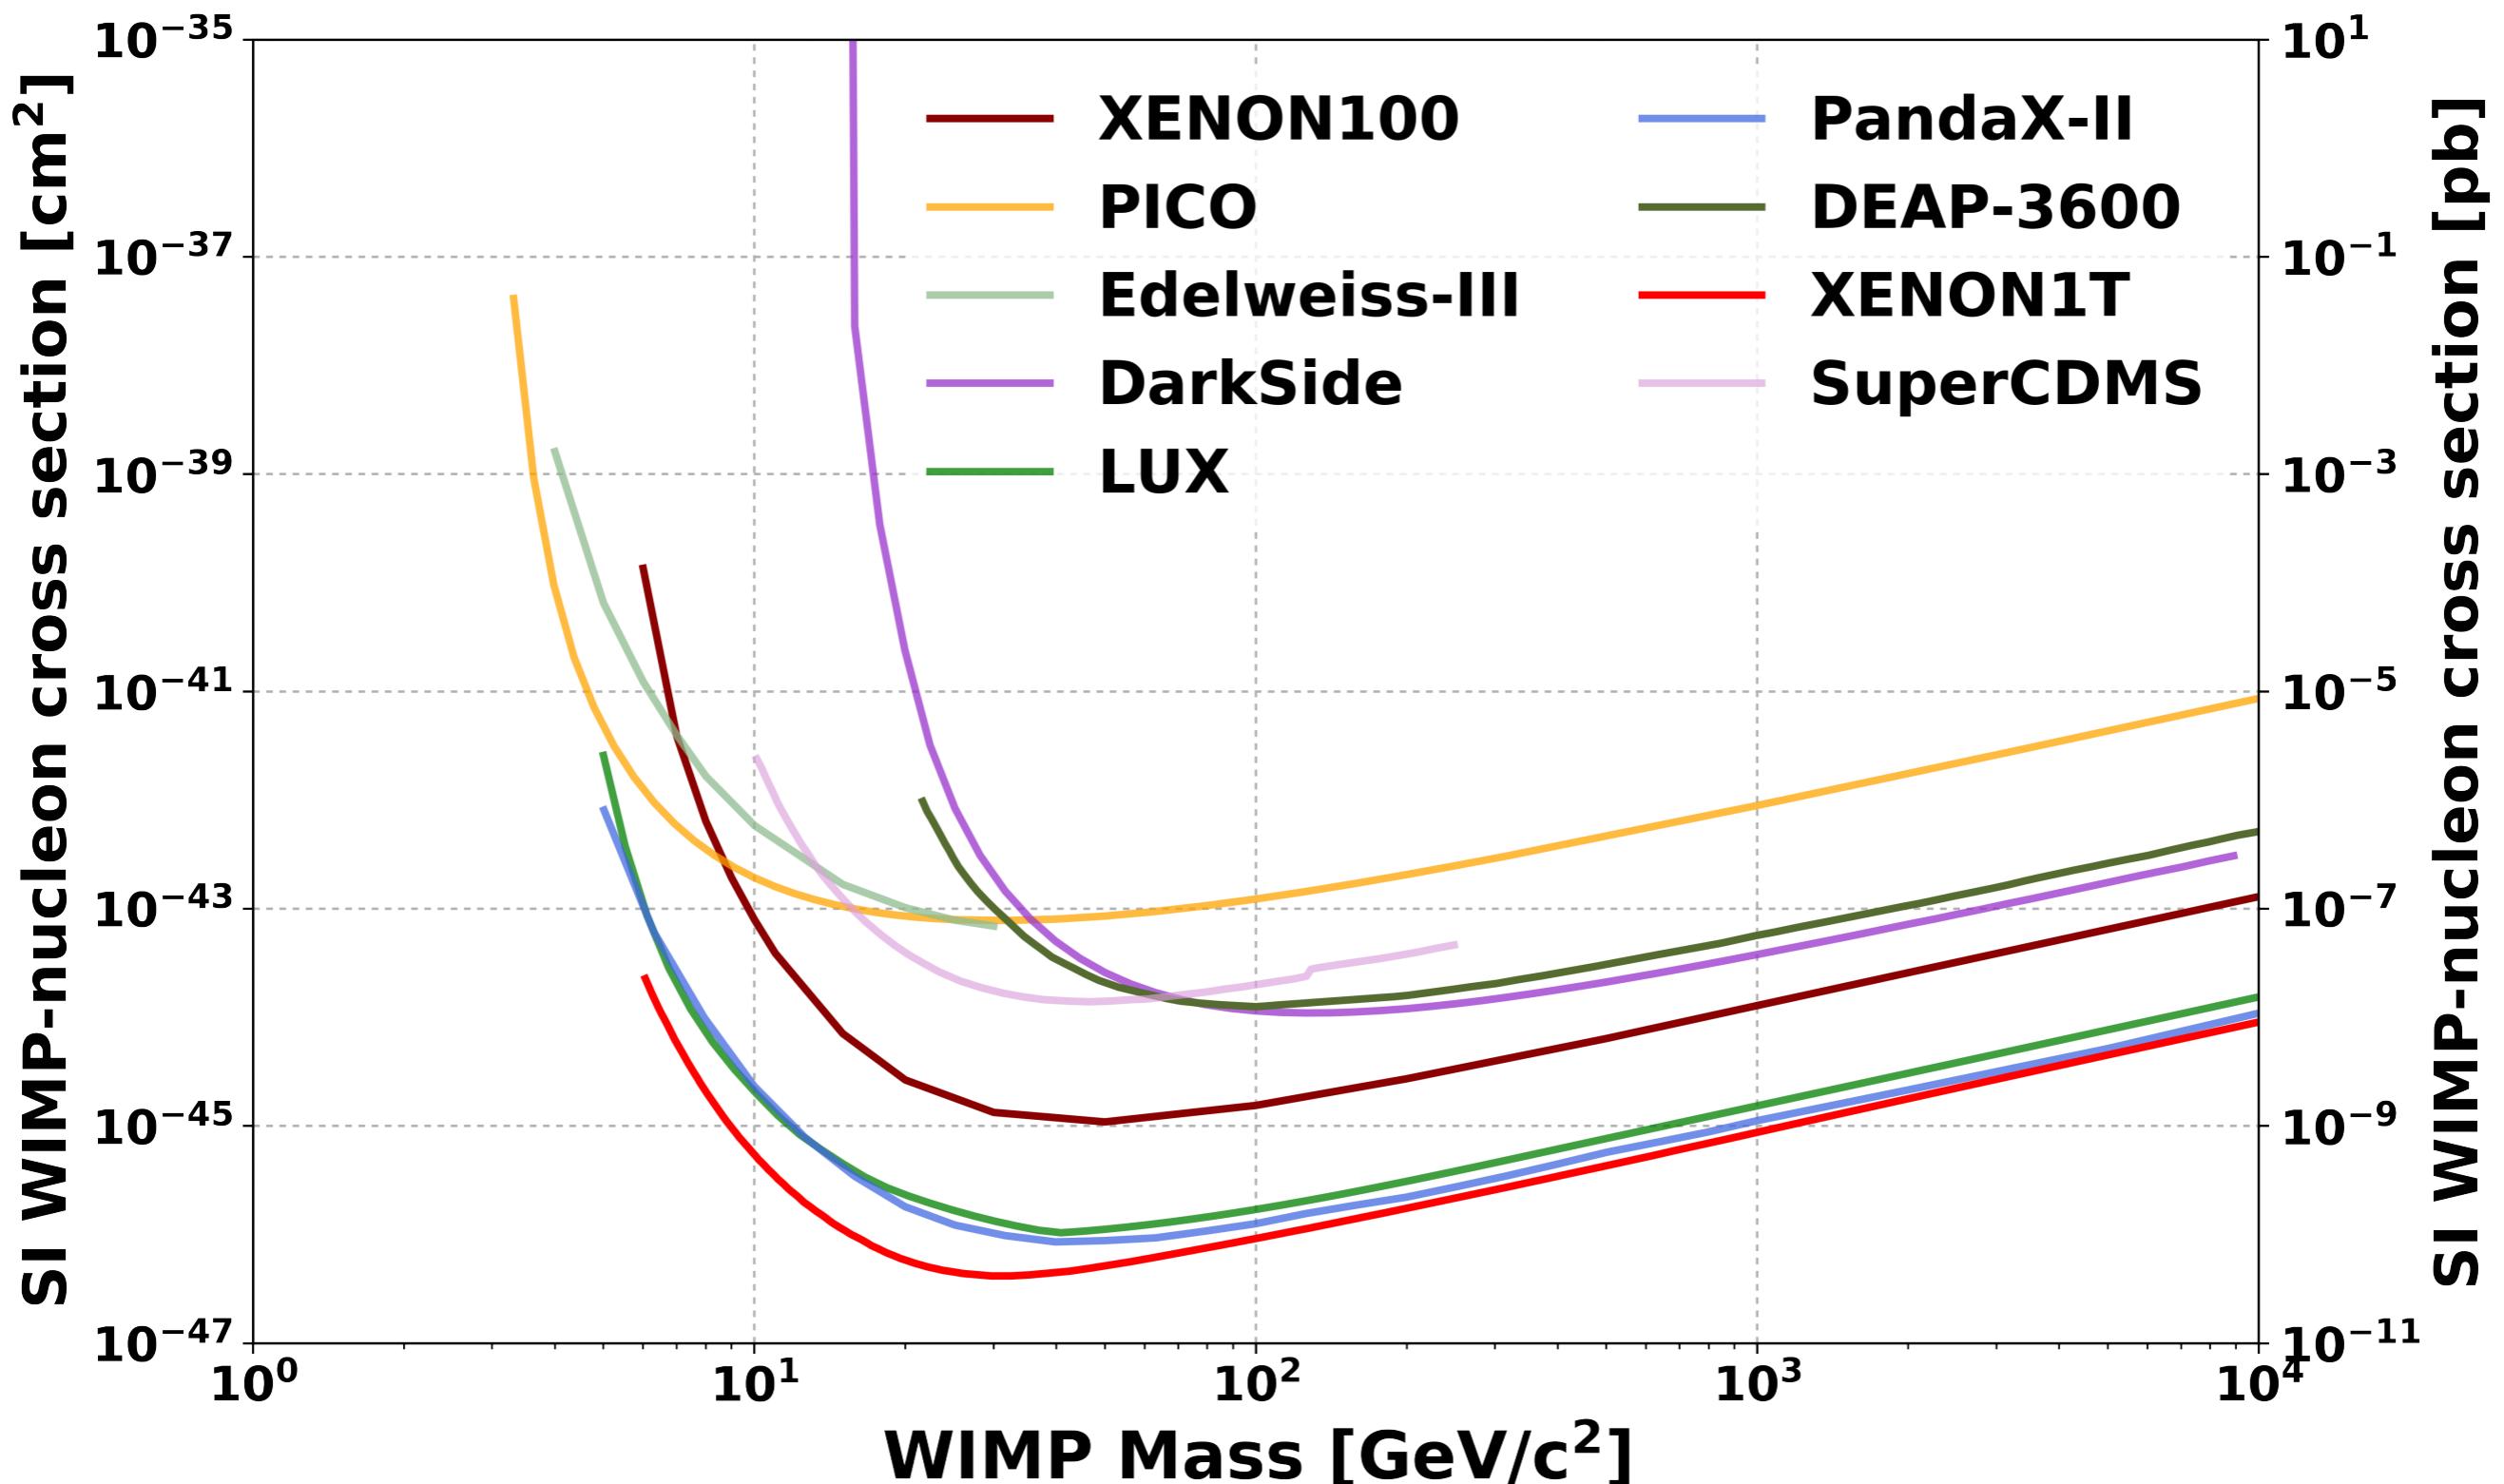

- no ER/NR discrimination
- low threshold: ~100 eVee
- bkg: ~1.5 event/keVee/kg/d at 0.5 keVee
- spectrum consistent with known background
- **Liquid argon now gives the best limits for low-mass DM between 2-5 GeV/c<sup>2</sup>**

# Low-mass dark matter search status

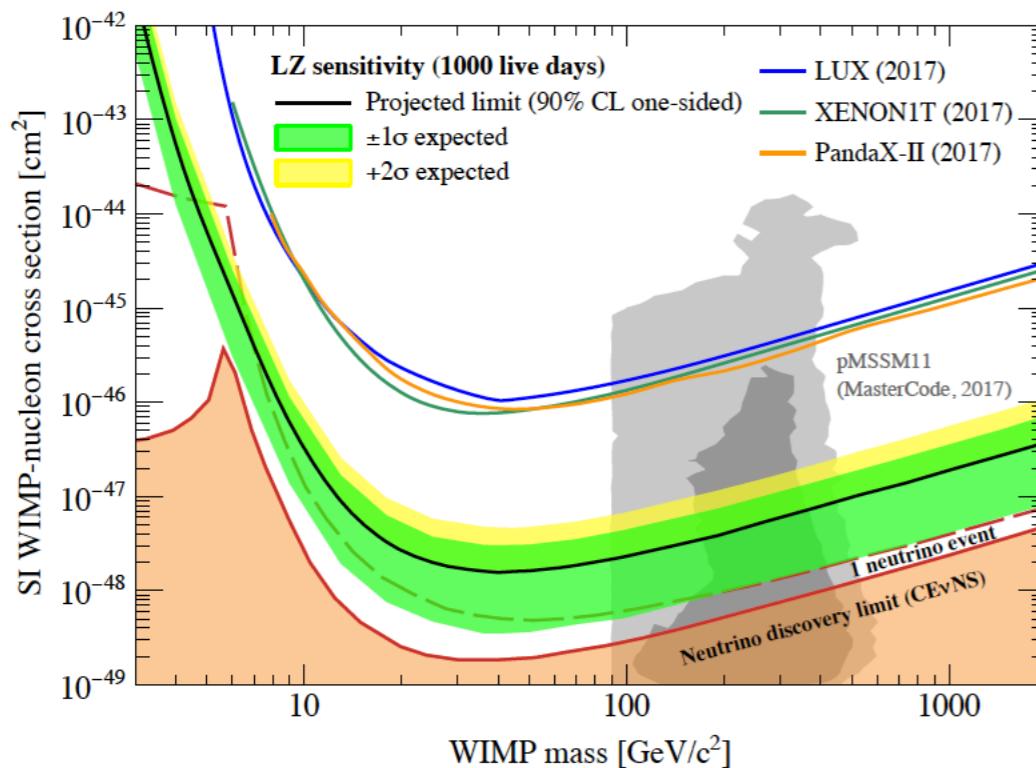

- 2~3 orders of magnitude above the “neutrino floor”
- challenges: background reduction/discrimination at the lowest threshold

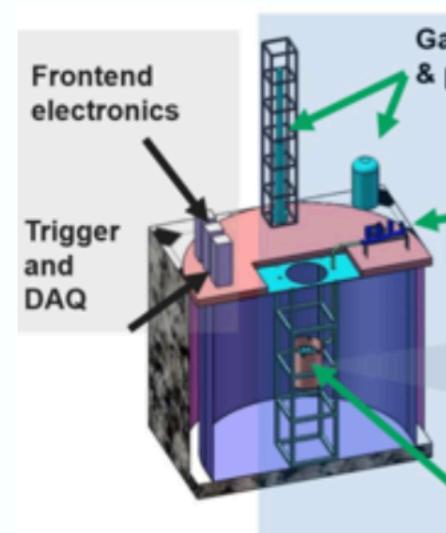

# Heavy WIMPs search: current status

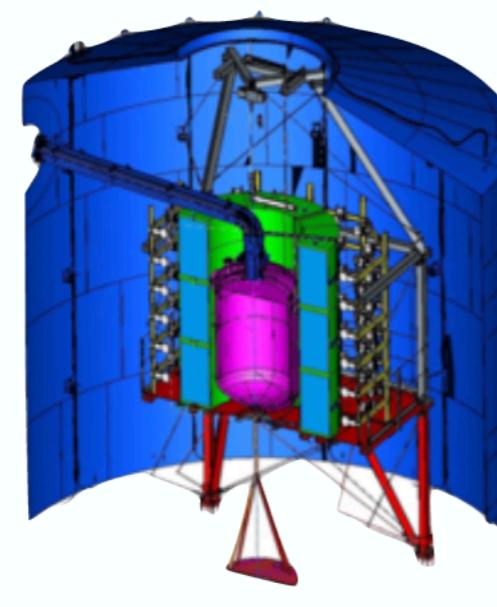

# LXe TPCs: the future

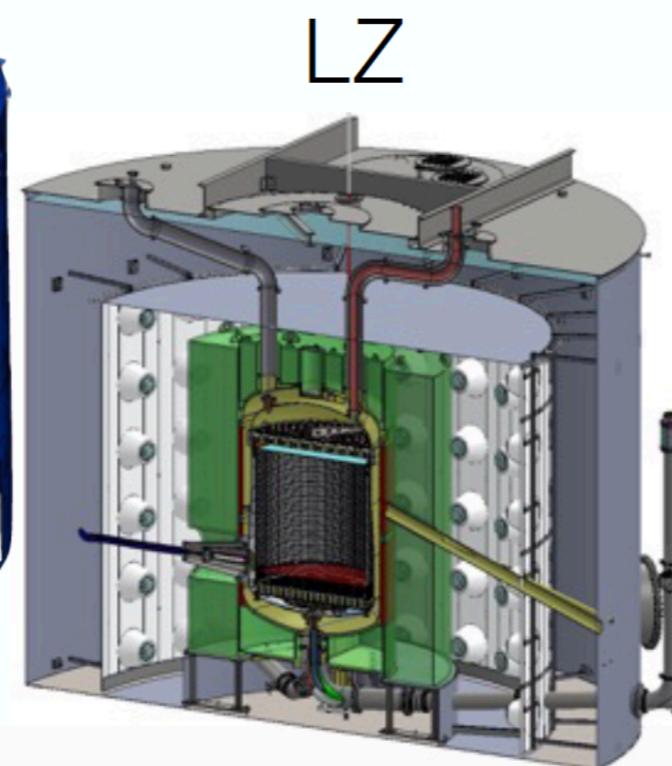

- Results from running experiments and secondary results from completed ones
- XENONnT: 2019 8t, 4t fiducial
- PandaX-4T: 2020 4t
- LZ: 2020 10t, 5.6t fiducial
- DARWIN: 2024 50t
